due to lead poisoning, 1 to brass or zinc, 1 to benzol, and 1 to petroleum products. Diseases of the skin recorded 2,060 cases, of which 6 were cancerous, due to pitch or tarry compounds. In only 793 of the skin diseases was there a disability of more than 7 days, i.e., 61 per cent had no compensable disability. The total number of days lost because of skin diseases was 39,020.

There were 89 claims for compressed air illness, most of them filed for medical treatment of painful conditions such as "blocked ears," painful teeth and neuralgia rather than real compressed air illness.

There were 450 claims for mineral poisonings, of which 441, including 15 fatal claims, were attributed to lead poisoning; the balance to brass or zinc. In 391 claims for lead poisoning, there was a loss of over 7 days, while in 35 it was 7 days or less. This would indicate that in one out of 12 claims there was a loss of less than 7 days, but if the loss was more than 7 days, the average period of disability was found to be about 87 days per case. The total number of days lost for the 441 lead poisoning cases was 124,196. From the standpoint of time lost, lead poisoning is the most serious of the occupational diseases encountered.

On July 21, 1929, tenosynovitis and prepatellar bursitis were added to the list of compensable occupational diseases, and since that time 26 cases were filed and found compensable, 12 for the former and 14 for the latter affliction. The total number of days lost was 671 and the compensation cost for the 26 claims was \$1,381.

Of the 561 claims which were filed for conditions not compensable under the Occupational Disease Law, 61 were for tuberculosis, 15 for asthma, 33 bronchitis, 52 for various poisonings, such as carbon monoxide, cyanide, chromium, etc., 44 for various infectious or contagious diseases, including scarlet fever, syphilis, pneumonia and various bacterial and parasitic diseases; 148 for various inflamma-

tory conditions of different parts of the body; 25 for neuritis, 8 for circulatory diseases involving the heart and arterial system; while 52 death claims were included in this group of non-compensable claims.

The table on costs shows a total compensation cost of \$278,515, or an average of \$104 for each compensable claim including the 18 death claims. The total medical cost is \$87,614, or an average of \$32 for each compensable claim.—

—Industrial Commission of Ohio, *Special Bull., No. 2*: 42–81, 1931. E. R. H.

Deep Mine Ventilation—There is a limit to acclimatization in moist temperatures which the writer, in his own case, some years ago, determined to be in a vicinity of 88° F. wet bulb. Beyond that the body temperature begins to rise continuously though slowly. In addition to the rise of body temperature, men in very hot places also suffer from what is really poisoning by water. During sweating the body is constantly losing salt as well as water, since the sweat contains about $\frac{1}{4}$ per cent of salt. A sufficient supply of salt, therefore, in either the food or drinking water, prevents ensuing trouble. About $\frac{1}{4}$ per cent of salt should be added to drinking water.

It is probable that the silicosis risk in dry air could be avoided if there were added to the quartzite dust another kind of dust with the property of rendering the silica harmless. Thus in British coal mines, the stone dust, which is either present naturally or is added in order to prevent explosions, does not produce miners' phthisis, though it contains about 35 per cent of quartz and nearly 60 per cent of total silica. The cost of dusting would probably be small in relation to diminished costs in other directions. One of the advantages is the abolition of risk of hookworm infection, and another, the very low death rate from tuberculosis (as experienced in British coal mines).

The next paper by the same author,

on "The Avoidance of Silicosis with Dry Methods of Working," points out that in the Rand mines keeping everything wet has not been an advantage so far as tuberculous infections occur, and that there is at present every reason for concluding that the dust danger in the mines could be overcome by the use of dry methods. This is especially so in face of the constantly increasing temperature encountered as the shafts reach lower levels.—J. S. Haldane, *Journal, Chemical, Metallurgical and Mining Society of South Africa*, 30, 2: 51-58 (Aug.), 1929. E. R. H.

A Study of Ventilation and Respiratory Illness in New York Schools; Comparison of Window-Gravity Ventilation and of Unit Fan Ventilation with Varying Air Flow—As in our Syracuse studies (Contributions Nos. 2 and 3) it appears that when school populations are balanced as to age, sex and nationality stock, and when the personal equation of the observer is held balanced, concordant and consistent results may be obtained from a study of school absenteeism and of respiratory illness among pupils in attendance.

A study of the health of pupils in schoolrooms ventilated by unit ventilators shows that reducing the rate of air flow from the standard figure of 30 cu. ft. per pupil per minute to approximately one-half that amount was not attended by any harmful effects so far as could be observed. In our experience the teachers preferred the rooms with low air flow on account of freedom from drafts and the lessened noise of the unit motors.

A comparison of schoolrooms ventilated with unit ventilators and of those ventilated by window-inlets with gravity exhaust shows that the simpler gravity process is quite as satisfactory from the health standpoint as is the system involving the use of fans.—Rufus Cole,

D. D. Kimball, F. S. Lee, G. T. Palmer, E. B. Phelps, E. L. Thorndike, and C.-E. A. Winslow (Chairman), *Am. J. Hyg.*, XIII, 1: 235-255 (Jan.), 1931.
E. R. H.

Heat Injuries Among Native Miners in the Witwatersrand Gold Mines—The critical heat point for man lies at an air temperature of about 90° F. wet bulb in the absence of appreciable air movement. In many of the deeper workings of the mines, men are exposed at air temperatures even beyond the critical point. Thus at a depth of 8,010 ft. the rock temperature was recorded at 101.2° F., the dry bulb, 94.2° at the drive face with machines working, and a relative humidity of 90 per cent, while at the top section of working stopes the dry bulb reached 96.2° and the relative humidity 95 per cent. With some 10,000 men, more or less, exposed to these conditions, there occurred, in 12 months, 12 cases definitely diagnosed as heat strokes of whom 6 died.

The principal symptoms exhibited by the victims were: Temperature 102° to 107°, axillary, but it is noteworthy that a few cases had a temperature of only 99° to 102°. Pulse 100-120. Dyspnea. Dry "burning" skin. Unconsciousness. Sometimes delirium and great violence were exhibited; one case was stated to require seven men to restrain him. Convulsions were present in most cases; in one there was a spasm similar to that seen in hydrophobia, so that he was unable to swallow. This is the nearest approach to "heat-cramp" of which I have a trustworthy record.

The majority of cases of severe stroke occurred in new workers. After the first week or two, gradual acclimatization takes place. Post-mortem, the striking lesions observed were edema of the lungs and brain, with acute congestion of these organs.

In the discussion, Dr. Hans Pirow, Government Mining Engineer, pointed out that the native laborer serves for a very short period and is then replaced

by another, so that in any one month they may deal with 10,000 or more new recruits, and the whole native labor complement is changed within a period of some 18 months. The question naturally rises whether the same standards of comfort are applicable to different types or races of natives. (A considerable important discussion follows, particularly in regard to advisability of decreasing wet methods and adopting Dr. Haldane's idea of dry methods through the mixing with the silicious dust of some harmless dust, since the wet methods now after a considerable number of years have not succeeded in eliminating miners' phthisis. At the Mysore mine, this result was alleged to have been attained, and he thought the method worthy of further trial.)—A. J. Orenstein, M.D., *Journal, Chemical, Metallurgical and Mining Society of South Africa*, 30, 2: 66-74 (Aug.), 1929. E. R. H.

Miners' Phthisis on the Rand—(We abstract only a couple of features from this valuable article.) The "New Rand Miners," meaning those especially selected since 1916, now number 8,300 and are increasing each year. The attack rate for silicosis among all miners who were working in their 10th year of service was 5 per cent, while among the New Rand Miners it was only 1.3 per cent.

It takes nowadays, on the average, over 12 years' underground work to produce a case of silicosis. Of the 270 cases detected during the past official year, 90 per cent had begun work prior to August, 1916—prior, that is, to the beginning of the present-day period.

While it is felt that a big corner has been turned in the matter of silicosis, it is not anticipated that the actual number of cases detected will show significant further decrease in the immediate future. After years of hard work on the part of mining engineers and inspectors and mine officials and medical

men, a large measure of success has been attained. But it is incomplete. When, in 1916, it was found that the liberal use of water would reduce the dust from drilling or blasting by as much as 98 per cent by weight, the problem appeared to have been solved. It was only solved *so far*. Have we not been overdoing water? Could we not do better with less water and a greater extension of alternative methods? (The dry dusting method of Dr. J. S. Haldane is then referred to.)—L. G. Irvine, M.D., and A. Mavrogordato, M.D., *Journal, Chemical, Metallurgical and Mining Society of South Africa*, 30, 2: 163-168 (Nov.), 1929. E. R. H.

Foundry Ventilation—The rules of the New York Industrial Code as enforced by the Department of Labor for the removal of smoke, steam, gases and dust, and for coremaking rooms in which women are employed, are reprinted, discussed, and methods of compliance illustrated.—John H. Vogt, *Indust. Hyg. Bull.*, New York State Department of Labor, 7, 9 and 10 (Mar. and Apr.), 33-34, 37-39, 1931.

E. R. H.

Compounding Materials Used in the Rubber Industry (Classification and Health Hazards)—The various substances used as accelerators, antioxidants, and dry organic compounds, are grouped as to toxic or irritant properties, and then arranged in alphabetical order and discussed. Special references are made to other Safe and Health Practices Pamphlets.—National Safety Council, *Indust. Safety Series* No. Ru. 1, 1931, pp. 16. E. R. H.

Benzol—The purpose of this pamphlet is to describe the principles used to protect the health of workers exposed to benzol. There are two distinct types of uses recognized, (1) that in closed systems of pipes or tanks, and

(2) in open processes. Benzol poisoning is briefly discussed as acute or chronic poisoning, with the most important diagnostic signs, also steps in medical supervision. Exhaust ventilation is discussed with diagrams and illustrations, while an Appendix is devoted to fire and explosion hazards.—National Safety Council, *Health Practices Pamphlet*, No. 14, 7, 1931.

The Effect of Prolonged Exposure of the Siliceous Spicules of a Fresh-Water Sponge (*Spongilla Fragilis*) to the Action of Animal Tissues: A Contribution to the Pathogenesis of Silicosis in Man—The spicules of the fresh water sponge, *Spongilla fragilis*, are composed of opal, a form of hydrated silica, which is similar to quartz in its chemical reactions. These spicules, when introduced into the tissues of animals, are slowly but definitely dissolved, proving conclusively that silica is soluble in the tissue fluids of animals, and presumably of man. This confirms the assumption held by many students of silicosis that particles of siliceous material are gradually converted into the colloidal state and as such exert a fibroplastic influence on the lungs of miners and other exposed industrial workers. Definite fibrosis of the lung of a dog into which the spicules had been introduced suggests that there is a concomitant injury attributable to the disappearance by solution of the siliceous elements of the spicules.—Ralph G. Mills, *Am. J. Hyg.*, XIII, 1: 224-233 (Jan.), 1931.

E. R. H.

Ultra-Violet Radiation and Resistance to Infection: Intranasal Infection with the Pneumococcus and with Bacterium Lepisepticum in the Rabbit—Three experiments with exposure to

direct sun or north skylight through vitaglass showed that both the percentage of infection and the morbidity rate after inoculation with pneumococcus type I was higher in the irradiated animals than in the control group kept inside.

Similar experiments performed with mercury arc radiation and infection with *Bact. leipsepticum* showed that radiation had no effect on the susceptibility to infection, although the mortality rate was somewhat lower in the irradiated group.

A variation in the amount of ultraviolet, from a marginal erythema to a heavy but subulcerating dose, had no correlation with resistance to the respiratory infections used.—Mary Hardy and Jeannette Chapman, *Am. J. Hyg.*, XIII, 1: 255-280 (Jan.), 1931.

Laboratory Aids in the Diagnosis of Lead Poisoning—Summary—

1. Laboratory methods for diagnosis in lead poisoning are valuable in any case, essential in the majority. They are not in themselves diagnostic but complementary to clinical examination including history.
2. In every case blood examination, including hemoglobin estimation, red blood count and examination of the stained smear, should be carried out.
3. Quantitative estimations of lead in the urine should be routine practice.
4. Public institutions such as public health laboratories should be in a position to make these estimations for the general practitioner.
5. In industrial work periodic examination of blood smears stained to demonstrate stippling in the red cells is a convenient and efficient method of checking exposed workers and, with practice, assists the industrial physician to place his staff of workers so as to avoid the more severe manifestations of lead poisoning among them.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Effect of Heat upon the Biological Value of Cereal Proteins and Casein—The first experiments by the authors were made upon certain prepared breakfast cereals. Rats 21 to 28 days old and weighing 35 to 60 gm. were used as test animals. Wheat, rice, and corn were tested alone and supplemented by small amounts of casein.

White bread was compared with the same toasted in $\frac{1}{4}$ " slices at 150° F. and bread crust similarly compared with the corresponding crumb. In each case, the toasted product caused less total growth and less growth per gm. of protein eaten. When 5 per cent of raw casein was added the discrepancy caused by the heat treatment largely disappeared.

Puffed wheat produced but little growth. Cracked wheat was then fed raw, toasted, and water-cooked. The growth value of the water-cooked was better than that of the raw, and both were greater than that of the toasted. Caramel formation during toasting was found to account for only a small part of the injury.

Raw cracked rice provided excellent growth but puffed rice gave far less growth.

Raw ground yellow corn gave less growth than did wheat, and toasted corn flakes gave less growth than raw corn.

When young rats were fed diets containing raw and toasted wheat gluten as source of protein at 9, 12, 15, 18, 21, and 24 per cent levels in a diet otherwise adequate, the growth in 56 days was found to be 1.29 to 1.40 per cent per gm. of protein eaten in the case of raw gluten at all levels up to 18 per cent, and to fall to 1.15 and 0.98 at the

21 and 24 per cent levels. The corresponding figures for toasted gluten were 0.94 to 1.09 and 1.12 and 0.86. The maximum growth rate on both raw and toasted diets was at the 18 per cent level, but the toasted gluten supported less growth than the raw both absolutely and relatively to the amount eaten at all levels.

When large mature rats were used for a similar study of raw and toasted wheat gluten at a 6 per cent level, the values found were 83 and 64 and in another test with raw and toasted casein at an 8 per cent level the biological values found were 66 and 53.

The digestibility of the toasted proteins was but little different from that of the raw, particularly in the older animals, and the unexplainable loss of nitrogen occurred chiefly in the urine, indicating that the change produced by the heat treatment lies probably in the assortment or availability of the amino acids absorbed.—Agnes Fay Morgan, *J. Biol. Chem.*, 90: 771 (Mar.), 1931.

Magnesium Starvation — Magnesium is present in many chemicals and in some drugs and is a necessary part of the normal diet, but how necessary it is and why has only recently been discovered by Drs. McCollum and Orent and reported by them at the Montreal meeting of the American Society of Biological Chemists. These doctors found that 11 days of a diet wholly lacking in magnesium caused convulsions and death in the majority of rats. On the 3d day of the magnesium-free diet the rats developed bright red ears and tails. On about the 10th day and never later than the 11th day the animals behaved

strangely. Slight noises agitated the rats so greatly that they whirled around two or three times and collapsed. Their breathing was disturbed, their eyes protruded and the blood rushed away from the vessels just under the skin so that the ears and tails were blanched. Eighty-five per cent of the rats died in the spasm, the remaining 15 per cent living on indefinitely, some as long as 90 days. When magnesium is omitted from the diet, calcium and phosphorus are drained out of the body so that not enough is left to make an X-ray of the skeleton. Dr. McCollum believes that this is explained by the fact that there is much the same relation between the adrenal glands and magnesium as there is between the thyroid gland and iodine or the parathyroid glands and calcium.—*Science*, 73, 1894 (Apr. 17), 1931, *Science News*, p. 10.

The Association of Vitamin A with Greenness in Plant Tissue.
III. Vitamin A Content of Asparagus Grown under Light of Various Qualities—In two former reports (Abstract, *A. J. P. H.*, Nov., 1927, and May, 1929) the authors submitted data leading to the conclusion that there is a relationship existing between the vitamin A content of plant tissues (lettuce and asparagus) and their degree of greenness.

The experiment reported here gives added support to the belief that in some manner or other the elaboration of vitamin A in the plant is connected with the development of the chlorophyll pigment.

Asparagus was chosen as the test plant. Twelve light filters were set in three frames and placed over the plants. A fourth frame was covered with Vita glass.

The laboratory procedure was practically the same as that of previous experiments. Albino rats were placed on a vitamin A-free ration, and when depleted of this vitamin were fed aspara-

gus taken from the region just below the terminal bud of the stalk. Growth was determined over a period of 8 weeks. This was in the 1929 season. Since the supply of tips was too limited to be used for other purposes the frames were set up again in 1930 and the tips used for determination of chlorophyll, amino acids, water-soluble nitrogen, and inorganic elements.

From the data on the chemical composition of the tips and the gains of rats in this experiment, it seems reasonable to conclude that within the restriction of the two variables expressed by some non-linear relationship chlorophyll content is a limiting factor on vitamin A synthesis in the vegetative parts of the plant. This gives point to the contention of a previous investigator (*Science*, 68, 48, 1928) that further progress in a knowledge of vitamin A may depend upon the industry and the success of the biochemists and the plant physiologists in the efforts to solve mysteries of chlorophyll and its functions.—John W. Crist and Marie Dye, *J. Biol. Chem.*, 91: 127 (Apr.), 1931.

The Use of Cottonseed Meal in the Diet of the Rat—These experiments were undertaken to establish evidence for the contention that cottonseed meal contains physiologically active gossypol in amounts sufficient to influence the growth and well-being of rats.

In these controlled feeding experiments, advantage was taken of the previously acquired information that iron salts are efficacious against gossypol injury and that gossypol is destroyed when heated to high temperatures in the autoclave.

The basic diet, containing cottonseed meal to which different amounts of iron salt were added, consisted of cottonseed meal (standard or autoclaved), yellow corn, wheat, alfalfa, NaCl, and CaCO₃.

A table gives the gain during successive 30-day intervals of rats on cottonseed meal diets supplemented with

iron. During the first 60 days all animals made normal gains but during the last 60 days of the experiment the rats receiving the standard meal without the iron additions almost invariably made smaller gains than the rats receiving the autoclaved meal. Marked improvement in growth resulted from the addition of iron (1 to 2 per cent of ferrous sulphate) to the standard meal.

At the close of the experiment the unhealthy condition of rats on the standard meal was very noticeable. At times the animals became extremely nervous or excited and breathed rapidly. The female rats appeared more susceptible to injury than the males.

Improvement in the growth and well-being of animals fed upon cottonseed meal diets was brought about in two ways: first, by administering inorganic iron, and, second, by replacing the ordinary meal in the diet with an autoclaved product which contains little, if any, active gossypol.—Willis D. Gallup, *J. Biol. Chem.*, 91: 387 (Apr.), 1931.

The Induction of Tetany in Rachitic Rats by Means of a Normal Diet—For many years the common method of inducing experimental tetany has been the removal of the parathyroid glands following which the calcium concentrate of the blood falls and the animal develops convulsions.

Another method is the feeding of large amounts of phosphates. Neither of these is satisfactory since they do not

resemble clinical tetany. The most common form of tetany is that which occurs in infants and an attempt was made by the authors to induce tetany in rachitic animals by means of a ration which approximated as nearly as possible the normal dietary of the infant.

Detailed descriptions and tables are given as to the experiments carried out. It was found that tetany can be induced in rachitic rats simply by an abrupt change from a rickets producing ration, high in calcium and low in phosphorus, to a normal ration of dried milk or of dried milk and whole wheat. The fall in calcium in the serum which is brought about by this means develops within 48 hours but is maintained for only a few days. This reaction is not due to an absolute nor to a relative increase of phosphorus in the dietary but to a sudden shift in the Ca:P ratio in the subsequent diet as compared to the preliminary diet. When this ratio of Ca:P is decreased from about 4:1 to 1, or 1.5:1, tetany ensues, whereas if it is decreased only to about 2:1 the fall in calcium and nervous symptoms do not come about.

Attention should be directed to the effect of marked alterations in the constitution of dietaries, as such shifts may help to explain nutritional disturbances which are not explained from the standpoint of adequacy.—Alfred F. Hess, Mildred Weinstock, H. R. Benjamin, and J. Gross, *J. Biol. Chem.*, 90: 737 (Mar.), 1931.

CHILD HYGIENE

RICHARD A. BOLT, M. D., DR. P. H.

PREVENTIVE DENTISTRY

A PROFOUND change is taking place in what was formerly considered preventive dentistry and mouth hygiene. In the past we have been occupied largely with the exploration of children's teeth—mainly during the school years—and the recording of numerous defects. An intensive program of pulling and patching was instituted and the children were instructed by tooth brush drills to believe that "a clean tooth never decays." Year after year this program was continued, and year after year we found about the same number of children entering our schools with defective teeth. The disturbing feature of this situation is that in a considerable percentage of these school entrants the first permanent molars have decayed beyond repair. This, as we know, may lead to various forms of malocclusion and systemic disorders.

So long as dentistry proceeded upon the theory that there was plenty of work for the dentist if he confined his practice to older children and adults, little progress in preventive dentistry could be expected. Fortunately the profession had a number of men, imbued with the research spirit, who were venturesome enough to attack the problems of the preschool child from all sides and even to peer into the mysteries of the prenatal period. From a knowledge of the embryonic growth and development of the jaws the first hints as to a more rational method of attack on problems connected with dental structure arose. This pioneer work in dental histology and pathology opened the way to clearing up many hitherto obscure points. But the greatest progress in clearly un-

derstanding the processes of growth and decay of the teeth has come in the last 10 years. During that time painstaking researches in the relation of nutrition to the teeth have been made. This work has been so carefully developed, and the check of one investigator upon another has been so thorough, that we may now point with a definite degree of assurance to the rôle of diet in preventive dentistry.

A painstaking review¹ of this subject, which it would profit every health worker to read carefully, appeared in the early part of this year. In this editorial review Dr. Hanke begins by pointing out that dental caries, pyorrhea alveolaris, and inflammation of the soft oral tissues have been known from the dawn of history and that man has held all sorts of theories concerning their causes. Man has also resorted to many fads and fancies to prevent and cure dental disease. In this article Dr. Hanke attempts to dispel present-day popular misconceptions. In summing up the evidence from antiquity he says:

These studies of the conditions that existed in ancient Egypt are instructive because they show that:

1. The mastication of coarse food does not prevent dental caries, suppurative periodontitis, nor pyorrhea; but it does wear down the teeth.

2. Unrefined grain does not contain mysterious substances that prevent dental disorders.

3. These dental diseases were associated with a diet that was predominantly carbohydrate, and was probably markedly deficient in vitamin C, and that was not necessarily inadequate in vitamin D.

4. Dental diseases are certainly not the outcome of modern civilization. (Although dietary deficiencies in the modern diet may be one of the factors, if not the main factor in dental decay as we see it today.)

It is pointed out clearly that "the changes observed in the teeth, the supporting structures, and the gingival tissue are considered to be metabolic in origin and not due to some local disturbance." If this is the case, as many investigators now believe, then the task of preventive dentistry is so to order the dietary of the pregnant woman and the infant as to make possible the proper growth and calcification of the teeth. Milk, green leafy vegetables and citrous fruits should be basic items, therefore, of the diet given the prospective mother.

Dr. Hanke also states that "poorly constructed teeth, delayed and irregular dentition, and slow development of the jaw bones frequently occur in children that have rickets." This lack of development, of course, predisposes the dental structures to disease. Experimental work with rats and dogs has made it possible to reveal some of the abnormal processes in tooth structure and shows that hypoplasia of the teeth leads to early decay in many instances. After a review of the work relating to scurvy, Dr. Hanke is convinced that

These considerations justify the conclusion that a deficiency in vitamin C may be a very important factor in producing pathological changes in the pulp, in the periodontal tissue and in the gingival tissue. This immediately throws a new light upon dental diseases and releases us from the shackles of the rather hopeless outlook that dental caries is a purely chemical process occasioned by the products of bacterial fermentation and that spongy gingival tissue and pyorrhea are due primarily to the ravages of bacteria that can hardly be removed from the mouth. It lays stress upon the metabolism of body cells. If we can produce healthy cells by proper nourishment, we can often eliminate the bacteria from the infected areas and keep them outside of the confines of the tissue.

While this last statement may lean toward too much optimism, it certainly makes the assumption that diet is a primary factor in dental hygiene appear worthy of following.

The most helpful suggestions arise

from the recent works of Sherman Davis; Boyd, Drain, and Nelson; and Bunting, Hadley, Jay, and Hard. All of these investigators stress the necessity of an adequate dietary although there are some differences in the details. For the child they recommend at least a quart of milk daily, one egg, a teaspoonful of cod liver oil, one ounce of butter, one orange, two or more servings of green vegetables and of fruits, and in addition any food the child enjoys which will go to make up the total caloric intake.

These investigators state that

Dental caries was arrested even when the major portion of the diet consisted of carbohydrate. This statement, which is in perfect accord with our own experience, calls for serious reflection on the part of many dentists, dietitians and biochemists who have persistently maintained that dental caries is the direct result of the over ingestion of carbohydrate. Many people ingest carbohydrates to the exclusion of the essential foods and the deleterious results of such nutritional habits may be due to the lack of vitamins and minerals rather than to excessive ingestion of carbohydrate.

The dental journals of the day carry articles calling attention to the newer knowledge of nutrition. The special care of the teeth during pregnancy is now looked upon as essential, not only for the sake of the prospective mother, but also for the developing fetus. Two recent issues of the *Dental Survey*² feature preventive dentistry from this modern viewpoint. Dr. Fairchild remarks:

To my mind prevention is the only solution of the pyorrhea problem. Ionization, emetine, vaccines, instrumentation, and drugs have all failed, but proper food has definitely given results. What a splendid thing it will be for humanity if children can be given the wonderful asset of fully developed jaws and soundly constructed teeth.

During the last year the *Journal of the American Dental Association* has presented a number of articles dealing with preventive dentistry and has set forth in its section on Health Education

many helpful hints of an educational nature.

The dentist and the physician must coöperate fully in extending the modern program for mouth hygiene and preventive dentistry. This must begin with definite prenatal instructions and continue until the full complement of teeth has arrived. If dentists can be brought to take as much interest in the preschool child as they now do in the school child

we may look for a great advance in mouth hygiene.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Where Do You Turn When You Want a Public Health Nurse?—One of the agencies to turn to is the Joint Vocational Service, Inc., 130 E. 22d Street, New York City. Here 4 years ago the social workers and public health nurses brought together their vocational centers.

Joint Vocational Service is not organized for profit; it is not even self-supporting, though the percentage income from registrants' placement fees and from subscriptions made by organizations using the Service is increasing year by year. About two-thirds of the volume of work has been in the social work field.

Due to the increasingly close relationship between social work and public health nursing, their united effort in conducting a vocational agency has proved more and more advantageous. The Service has also been working closely with the Education Committee of the National Organization for Public Health Nursing.

In the past 4 years nearly 2,600 public health nurses registered or re-registered with the J. V. S. Of these about three-fourths were high school graduates, and most of the high school graduates had had college work also. Nearly 500 were college graduates, and many of these had taken postgraduate work.

During 1929 and 1930, J. V. S. filled 492 public health nursing positions and assisted in filling 125 more. The percentage of placement in public health

nursing has been higher than in the social work field, probably because it is more nearly standardized.

In the past year the number of available positions in public health nursing declined 15 per cent. The decline was most noticeable in beginning staff positions and in executive positions.

Most of the positions filled were in the area around New York City, but the agency has also been reaching out through the country. The number of positions reported from the Mid-west and West have increased considerably.

J. V. S. has filled public health nursing positions at salaries ranging up to \$5,000 but the largest number of positions without maintenance offered about \$1,800; with maintenance about \$1,200. Comparatively few positions without maintenance have offered \$2,600 or over; few with maintenance have been available at \$2,000 or over.

—*Report of Progress, Joint Vocational Service, for year 1929-1930, pp. 1-4.*

Something New in School Nursing—School nurses in New York State are now called school nurse-teachers. They are certified by the teacher training division of the State Educational Department and must have the following qualifications:

1. Graduation from an approved four year high school course or its equivalent
2. Graduation from a nursing school registered by the regents of the university
3. Certification as a registered nurse in New York State
4. Completion of at least 6 semester hours in approved professional courses in health education

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

The term "health teacher" no longer applies to a school nurse-teacher. A "health teacher" must have completed the professional requirements in general teacher-training courses covering a minimum training period of 3 years, specializing in the field of health and hygiene. Nurses' training is of value but is not a requirement.

There should not be more than 1,500 school children to one school nurse-teacher, and in rural districts where the distances are greater, 500 are often as many as a school nurse-teacher can serve.

The trustees or boards of education of two or more districts may unite in employing a school nurse-teacher and where she meets the state requirements the state will pay half the nurse's salary, or \$700 as the maximum.

The school nurse-teacher never makes the annual medical examination; that, of course, must be made by the school medical inspector, but in the smaller communities, which he visits very infrequently, she gives most of the health service under his direction.

The education department has defined the function of the school nurse-teacher thus:

The primary function of the nurse-teacher shall be to assist the school medical supervisor (school physician or medical inspector) and other school officials in protecting the health of school children; by assisting in examining pupils; by rendering first aid service; by visiting homes; by making health inspections of the school plant; and by such other health protective duties as are permitted by law and may be prescribed by the board of education. The secondary function of the school nurse-teacher shall be to teach health habits and health information through contacts with individual pupils, parents, and teachers. The nurse-teacher shall not be regarded as a classroom teacher nor engage regularly in hygiene instruction in classrooms.

Usually the school authorities find it an economy to furnish the school nurse-teacher with some means of transportation. Often the correction of defects found by the school medical inspector cannot be secured without a

home visit by the nurse; in many ways the contact the nurse furnishes between the home and the school is a valuable feature. Without proper transportation facilities it must of necessity be very limited and very expensive.

The Education Department of Newark, N. J., has educational requirements for the school nurse similar to those of New York State.—Marie M. Ready and James F. Rogers, M.D., Legislation, Biennial Survey of Education in the United States, 1928-1930, U. S. Dept. of the Interior, Office of Education, *Bull. No. 20*, 1931, pp. 26-27.

A New Visiting Nurse Association—Student Nurse Combination—For some time certain nursing schools have had affiliations with public health nursing associations or visiting nurse associations to give senior nurses 2 months' training in public health nursing, but the Visiting Nurse Association of Brooklyn, N. Y., one of the earliest established in this country, has gone further even than this in affiliations as explained in the April *Survey*.

The association has formed a "pediatric affiliation" with two of the hospitals in the city to supplement their training of the student nurses in the care of children. At the present time the hospital experience alone is not sufficient to meet the requirements of the New York State Department of Education. The association gives a 6-weeks course to groups of 14 students at a time, consisting of about 8 days of observation in the homes with staff nurses, classes and demonstrations in the care of sick children in the home, and health supervision of infants and preschool children. Time is given for reference reading and for excursions to various health agencies interested in work with children. The remaining time is given to actual field experience and to case study of family health problems.

—The V. N. Teaches the Student, *Mid-monthly Survey*, Apr., 1931, p. 98.

Correspondence . Schools for Nurses—A timely article has been written by the Bureau of Publicity of the Indiana State Medical Association

that applies to the whole county and we are quoting it:

Becoming a trained nurse by correspondence is as impossible as learning to be an aviator in a bird store. Yet correspondence schools for nurses are in existence which advertise that by taking their courses a person may fit herself for nursing. Several such schools are established in the Midwest and the Bureau of Publicity of the Indiana State Medical Association receives many requests each year in regard to the value and standing of these institutions.

In answer to these requests the Bureau quotes from a bulletin entitled "A Fraud upon the Public—There Is No Angle from Which Advertising of Correspondence Schools of Nursing Can Be Justified," recently issued by H. S. Cumming, Surgeon General of the U. S. Public Health Service.

"To anyone who has ever needed the services of a nurse, the necessity for thorough training must be apparent. Thorough training cannot be and never will be possible through correspondence, for nursing is a profession requiring a technical skill in the performance of many difficult procedures which can come only from doing them over and over again. Yet one constantly sees advertisements of 'correspondence schools of nursing,' 'learn nursing in your own home,' etc.

"The trained nurse must know the ebb and flow of the vital forces. She must be familiar with the danger signals that mark the safe course to recovery. Her mettle must be

known by those who vouch for her. What will she do in some dramatic emergency in the operating-room, when quick team work is necessary, or in the silent watches of the night when alone in the ward she holds grave responsibilities? How shall a textbook, alone, describe the indescribable look on a patient's face in the split second preceding catastrophe, when life and death hang in the balance?

"Even the rudiments of nursing cannot be taught by correspondence. To attempt to teach nursing by correspondence is as impossible as it would be to teach medicine.

"No less great than the imposition on the public is the imposition on the young woman who is given to understand that this training is adequate for her to earn her living as a nurse.

"Many requests come to the Public Health Service for appointment in government service from graduates of correspondence schools. They are naturally not eligible for appointment; they cannot get any position under Civil Service, state or federal; their only hope is to receive calls from a private practitioner. Many young women also write this department asking whether a course in a correspondence school will fit them for nursing. In every instance they are advised to enter an accredited school of nursing."

—Correspondence Schools for Nurses, News Release, Bureau of Publicity, Indiana State Medical Assn., Apr. 27, 1931.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

CONVENTIONS—MEETINGS

The announcement of the annual conference of New Jersey health officials included the following:

Six New Jersey health officers will tell how they put across new plans last year. A wide variety of projects is to be covered by this group of talks, such as monthly letters to physicians, vaccination clinics, coördinating nursing activities, filing vital statistics, taking

a preschool census and conducting tuberculosis campaigns. These will be short stories of real accomplishments, not theories.

Yes, there will be a playlet. Last year's experiment was so successful that a new demonstration playlet has been prepared for everyone's enjoyment and edification.

If you give talks or demonstrations on nutrition be very sure to look up "How To Interest Men and Women In Nutrition," by L. A. Case. *Journal of Home Economics*, 101 East 20th St., Baltimore. Sept., 1930. 30 cents.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Suggestions for Planning Meetings—American Nurses' Assn., 450 7th Ave., New York. A mimeographed outline. (It is dated!) Useful for staff or local group meetings. Section on "Planning a Meeting" could help a lot of meetings planned by health workers. The meeting outlines from Wisconsin seem entirely too full. The numerous "ten-minute discussion" topics call for high pressure methods. Surely they should be extended to 20 or even 30 minutes for anything like real discussion in a group. As planned they could only be handled as 10-minute speeches—and concise ones at that. It is good to note the increased use of detailed memoranda on specific work problems. *10 cents.*

"Health At Winter Meetings"—Connecticut Dept. of Health—outlines an offer to send speakers—lists topics and offers illustrative material.

A "Publicity Clinic," conducted by A. Schaeffer, Jr., Natl. Tuberculosis Assn., was a feature of Indiana Tuberculosis Assn. annual meeting.

"The Relation of School Nursing to Health Education," and "How the Nurse Can Aid Classroom Teachers in Promoting a Sound Program of Health Instruction"—topics in a School Nurses' Institute conducted by Connecticut State Dept. of Education.

Because of the World Federation of Education Assn. meeting at Denver, July 7–Aug. 1, with its Health Section, the American Child Health Assn. will not hold its usual Sayville conference this year.

BULLETINS—HOUSE ORGANS

These notes are intended to suggest topics and sources for copy, in addition to offering comment on typography and other details in getting up house organs.

Some of the bulletins issued more or less regularly—especially mimeographed issues—are dated, but lack number and volume. At least consecutive numbering would be a simple matter.

Guessing contest—which city health department uses 6 different kinds of type on the cover page of its house organ?

An early start in Iowa—a "Tourist Camp Sanitation" issue of *Iowa Public Health Bulletin*, State Dept. of Health. Jan.–Mar., 1931. *Free.*

Copy on automobile accidents may be found in the Apr., 1931, *Travelers Standard*, Hartford, Conn. *Free.*

A "news photograph" on the title page of Jan., 1931, *Bulletin*, Milwaukee Health Dept. A smiling girl—holding card ("How's Your Health?" etc.)—caption: "Start The Year With a Health Inventory." *Free.*

Effective use is made of several sentence statements on the lower half of the cover page of *Pittsburgh's Health*, Dept. of Public Health. The page would look better if the whole of that page could be set in the same type—using different sizes—with no italics. *Free.*

Better Health, Dept. of Health, Syracuse, N. Y. Mar., 1931. "Easter Greetings" cover design—purple ink—includes "Mother Goes to School" and "Ordinances You Should Know." *Free.*

"The Citizen and Health" (*Bulletin*, Milwaukee Health Dept. Feb., 1931) is a page abstract of Prof. Winslow's Fort Worth address—which address could be used widely to advantage for pointing out the minimum of public health knowledge for every citizen.

Dairy Council Digests—Natl. Dairy Council, 221 N. LaSalle St., Chicago. Monthly reports on diet research for those who wish the latest developments. *Free.*

"The Department of Health 38 Years Ago," by Dr. A. R. Reynolds, suggests an idea that would make an interesting article in many a town or county. *Weekly Bulletin*, Chicago Dept. of Health. Feb. 24, 1931. *Free.*
Baltimore Municipal Journal (Feb.

20, 1931) tells about "The Health of Our City 135 Years Ago—Today." In that day there was yellow fever. *Free.*

Harlem Health Bulletin, issued by Harlem Tuberculosis and Health Committee, 108 West 136th St., New York. A mimeographed bulletin on half letter size sheets, green paper, double red cross printed in corner of the top sheet. Contents illustrate activities in a Negro district, and a distinctive form of bulletin. *Copy free.*

The Michigan Sanatorium Assn. utilized the Jan., 1931, issue of *Michigan Out of Doors* (Michigan Tuberculosis Assn., Lansing) to acquaint the state with the tuberculosis sanatoriums. The body of the issue is made up of large page half-tones which "bleed" over the edge of the pages—descriptive text and smaller pictures on the right side. An 8" rule with 3 light rules at the right of the text cuts down length of text line—gives interesting effect. If readers "bleed" photographs we suggest that they try a grey or black 8" line on the inner edge of the photograph so that it won't seem to run under the opposite text page. *Free.*

The "Public Health Nursing" issue of *The Commonwealth* (Oct.–Dec., 1930), Massachusetts Dept. of Health, includes: "Education and the Public Health Nurse"—"Staff Education"—"Group Education in Small Communities"—"Post-Graduate Education"—"Parental Education in a Public Health Program." *Free.*

"Putting the Layman Wise on Cancer" is the theme of Feb., 1931, issue of *Health*, New Haven Dept. of Health. Fine title—good text in 2 short articles for the "Layman." *Free.*

Quarterly Bulletin, Frontier Nursing Service, Lexington, Ky., gets a pleasing effect by use of an ivory dull-finish paper. *Free.*

"Selling Health In Industry," by H. H. Keller. *Pennsylvania's Health*, State Dept. Jan.–Feb., 1931. What

the Bell Telephone Co. of Penn. does. *Free.*

Tidings is the multigraphed bulletin of the Division of Child Hygiene, Massachusetts Dept. of Public Health. The size, 5¾" x 8½", printed cover, some illustrations, stapled—gives an interesting variation from usual practices. *Free.*

EDUCATIONAL

"Food Plan for Family of Five at \$7.50 a Week"—Public Health Federation, 312 W. 9th St., Cincinnati. 4 pp. An inadequate emergency diet. *Free.*

"Health On The Farm and In The Village," by C.-E. A. Winslow. The pamphlet contains "Outstanding Lessons of the Cattaraugus County Health Demonstration," a chapter from the full report. Milbank Memorial Fund, 49 Wall St., New York. *Free.*

"The High Cost of Personal Neglect," by Dr. J. Clark, 114 East 54th St., New York. Reprint from *Hygeia*. Jan., 1931. A plea for periodic examinations. *Free from the author.*

"How To Train Your Baby To Keep Dry"—Massachusetts Society for Mental Hygiene, 3 Joy St., Boston. 4 pp. Good sample of size, paper, typography. *5 cents.*

"Illness and Dependency"—"Private Group Clinics"—two recent issues of Committee on the Costs of Medical Care, 910 17th St., N. W., Washington. *Free.*

"Lightning!"—Health Dept., Racine (One knows the city if one remembers Dr. Bauer's address!—not given on the folder). A good 4-page folder on smallpox. *Free.*

"We Ask Your Help!" (excluding child from school); "Pointing the Way" (reporting school physician examination)—school examination appointment card for presence of parent—Racine Health Dept. *Especially good text. Free.*

"Milk Every Meal: Morning, Noon,

Night"—College of Agriculture, Madison, Wis. 8 pp. *Sample free.*

A New Year's Greeting folder—contents adaptable for use anywhere at any time of the year—Public Health Nursing Out-Patient Dept. of Englewood (N. J.) Hospital. "Around the Day with the Nurse in Gray" in 7 photographs with *good captions*. 4 cents for copy.

"A Program of Life for All Who Desire to Live Long"—Alabama State Board of Health. 8 pp. Not dated. Fourteen points grouped under "Habits," "Air," "Food." Could be used as 14 daily "boxes" in a newspaper. Could we cut the title to read: "How to Live Long?" *Free.*

"Scarlet Fever"—another of the miniature booklets issued by John Hancock Life Insurance Co., Boston. 8 pp. Tells what most needs to be known—and about all that most people are willing to learn. *Free.*

"We Used to Think—Wrongly: We Know Now—For Certain"—Brooklyn Tuberculosis and Health Assn., 293 Schermerhorn St. 4-page folder—rough finish paper—inside pages contrast old ideas with current knowledge. *Free.*

"Whooping Cough"—"Measles"—"Scarlet Fever"—"The Family Teeth"—"Diphtheria Costs! Prevention Pays!"—5 4-page folders on good quality rough finish paper—each different color—source indicated in small type on last page: "Tennessee State Dept. of Public Health—Nashville, Tenn.—1930." *Samples free.*

TIMELY

Some of the material listed below will be too late for use this season, but now is the time to secure copies for use next year.

"What Health Officers Do"—*Bulletin*, Indiana Board of Health. Oct., 1930.

"Nineteen Thirty the Best Health Year"—*Statistical Bulletin*, Metro-

politan Life Insurance Co. Jan., 1931.

"The Hollywood 18 Day Diet"—*Hygeia*. Mar., 1931. What is wrong with it—and why.

"Scarlet Fever and Measles." Radio talk. New York City Dept. of Health. *Free.*

"Improved Drinking Facilities in Places of Employment"—*Municipal Sanitation*, 24 W. 40th St., New York, N. Y. Feb., 1931. 25 cents.

Unemployment: "Hard Times and Health"—*The American Public Health News*; "Economizing Wisely"—Connecticut Dept. of Health; "Keep Up A Clean Front"—*Cleanliness Journal*, Cleanliness Institute, 45 E. 17th St., New York, N. Y. *Free.* "How baths and fresh collars help when jobs are scarce."

Carbon-monoxide poisoning: *Pittsburgh's Health*, Dept. of Health; Connecticut Dept. of Health (press); *The Foreman*, Employers' Mutual Liability Ins. Co., Wausau, Wis. (good 4-line analysis). *Free.*

Colds: Iowa Dept. of Health (press release); Illinois Dept. of Health (radio talk); Connecticut Dept. of Health—also "Effective Temperature" (press); New York State Dept. of Health (radio); Detroit Dept. of Health (press); Oregon Board of Health—fresh air (press); *Chicago's Health*, Chicago Health Dept.; New York City Dept. of Health (press); "The Billion Dollar Loss From Colds," *Hygeia*. Feb., 1931.

Pneumonia: Detroit Dept. of Health (press); U. S. Public Health Service (radio).

"How to Keep Warm in Winter" (the house, moisture, warmth in bed, etc.—much neglected topics), Rochester Bureau of Health (monthly bulletin).

MOTION PICTURES

"Test for Titles," by A. L. Gale. *Movie Makers*, 105 West 40th St., New York, N. Y. Feb., 1931. 25 cents.

"What to do and not to do when you

are writing titles." *Very practical and helpful.*

A carbon monoxide picture has been made by the Bureau of Mines in co-operation with an automobile company. Where c.m. develops and how to avoid its perils. *For transportation charges.* U. S. Bureau of Mines, Pittsburgh, Pa.

"The Hit That Scored," said by a number of safety people to be the best one-reel public safety film they have ever seen, has been produced by the Bell Telephone Company of Pennsylvania.

The film shows in an unusually interesting and realistic fashion some of the adventures of a good natured but reckless truck driver who believes in bluffing the other fellow—until an accident that almost causes the death of a little girl teaches him the lesson of safe driving.

The film has been found to be very effective without being in the least gruesome, according to those who have viewed it.

Apply to National Safety Council, 20 N. Wacker Drive, Chicago, Ill., or Citizens' Safety Committee, Philadelphia Chamber of Commerce.

Movie Makers (Feb., 1931) reports on two amateur pictures which illustrate two different possibilities:

To serve in the membership drive of the Crippled Children's Clinic, Birmingham, Ala., which organization provides free of charge orthopedic attention to children unable to pay. The Long Journey, 1,600 feet, 35 mm., produced by Jack London, has recently been completed. Making of the film required between ten and eleven months, it being necessary to film the children on their entry to the Clinic and again several months later when they were on the road to recovery.

Showing of the film to the Shriners' Club alone resulted in over \$900 in memberships for the Clinic, Mr. London reports. Since the cost of producing the film was in the neighborhood of only \$246, the actual cost of material, Mr. London having contributed his services as cameraman, the value of an amateur production in fund raising is again forcibly demonstrated.

An Auto Biography, the one reel 16 mm. film on accident prevention produced by Jack Lewis, Wichita, Kansas, is now being used in the intermediate schools of Wichita in con-

junction with a talk by a traffic officer. Several of the schools have booked the film for a second showing to follow two weeks after the first. The film has also been shown at Chamber of Commerce and Lions Club meetings and has, at the request of the street car company, been projected for their employees.

ADVERTISING

One easy step every health worker can take to help combat fake or extravagant advertising is to send copies to the National Better Business Bureau, Chrysler Bldg., New York, N. Y. If your newspaper editor is cooperative you might urge him to check doubtful advertising by writing to the above address.

Whatever you do—and it is reported to the editor—we will give you credit in the "Advertising" section of Education-Publicity Headquarters at Montreal.

Advertising & Selling, New York, N. Y., gives a full page to an advertisement quoting the Health Officer of Poultney, Vt., congratulating the American Cigar Co. for "fighting the Spitting Evil"—along with a letter to the editor in which the Health Officer explains that

I had no idea that it was to be used for advertising purposes, but understood that it was merely for my opinion on spit tipping and spitting in general.

The Health Officer now agrees that it is unwise to write a letter of commendation "without giving it due consideration."

NEWSPAPERS

"The biggest newspaper story that could break today" was suggested to *Editor and Publisher* by leading newspaper editors. Three or four suggested that it would be the "announcement of an absolute and indisputable cure for cancer."

David Lawrence, editor of *United States Daily*, addressed the annual meeting of American Social Hygiene

Assn. upon "The Function of the Press in Social Hygiene Education." He stressed the need of skillful preparation of material for the press.

Although health workers have been emphasizing the unwillingness of newspapers to mention the names of the venereal diseases, at least one city health department follows the same policy in its annual report. "Social Diseases" is as far as that health officer will go.

For about 12 years, every week, "Our Babies," a newspaper column on the care of babies, has been issued by Royal New Zealand Society for the Health of Women and Children, Dunedin, New Zealand.

Letters to editors and citizens are being sent out by Tennessee Tuberculosis Assn. in opposition to an effort to reduce the appropriation for the State Dept. of Health.

NEW

Eugenics, American Eugenics Society, New Haven, Conn., has become *People*. "A popular magazine of human biology and the manner in which it may be manipulated to achieve the improvement of the race."

EXHIBITS

Now is the time to start preparations for state and county fairs.

Numerous suggestions as to planning and making exhibits will be found in this department of the *Journal* running back several years.

A memorandum of several pages on fair exhibits will be sent upon request to the editor.

Last summer the Illinois State Dept. of Health demonstrated a homemade milk pasteurizing outfit which need cost less than \$5.00. Ask Illinois for details.

Connecticut State Department reports that weighing of the children is one of the interesting features of the

health exhibit of the State Department of Health. It gives the staff in attendance an opportunity to discuss health with the parents and incidentally it is found that parents themselves are the chief offenders in breaking health laws.

Thousands are attracted to the health exhibit at the fairs. There is a continuous showing of health films and many hours during the day the health tent is taxed to the utmost. At a fair which extended into the evening hours the films program had to be frequently interrupted to clear the tent and provide fresh air and ventilation, the pictures proved to be so popular.

Advice given by *Red Cross Courier* seems to apply to displays by other organizations:

Simplicity in conception for an exhibit or a float is its own reward. Our own people know that to concentrate attention upon one or two objectives serves to retain them in the mind. Perhaps, because of the multiple services rendered by the Red Cross, our exhibits and floats have been somewhat complicated. That is natural, for every one wants to tell a story in all its detail. However, telling a story and presenting it as a picture are very far apart—for the picture, to be effective, must have a central theme, a high light of the important element of the composition. In other words, in an exhibit or a float the mental processes are animated by the striking thing. The eyes focus on one point and see that one thing. Consequently to do the best to visualize Red Cross to the spectator, it is well to remember that simplicity and concentration upon the central picture are always advisable.

"How can I cultivate in my children a zest for food?" might be the theme of an exhibit. "That Zest for Food," by Rachel Ash (*Hygeia*, Oct., 1930), includes some of the possibilities for exhibit use.

The Community Health Association was represented in a big Boston parade by

A delegation of nurses who marched, led by one dressed as the first district nurse in Boston, of 1886. A striking sign carried by boy

scouts explained it all in a few words. The entire group attracted much attention and favorable comment.

"The International Exhibition of Hygiene, Dresden, Germany," by S. A. Cosgrove, M.D. *Public Health News*, New Jersey Dept. of Health. Dec., 1930. An excellent outline of the displays. *Free*.

"Overworked Spot Maps," by E. J. Reeder. *Public Safety*, Natl. Safety Council, 20 N. Wacker Drive, Chicago. Mar., 1931. Illustrates spot maps for automobile accidents; their value; what to use and not to use. Also, "Outdoor Displays," by L. W. McIntyre. How Pittsburgh is using startling three-dimension exhibits in open spaces. *Free*.

The New York City Cancer Committee, 34 East 75th St., has devised an unusual traveling exhibit. A group of 6 boxes provide a series of stages in which miniature scenes are displayed. The boxes make for easy transportation about the city. They are built up in pyramid fashion—on a table, or in a window on a low platform. Characters and backgrounds are cut outs, lacquered in colors. Each is removable so that new material may be inserted in the boxes. The boxes are in black lacquer with monel metal binding strips. Designing and executing the exhibit cost \$1,000, with \$600 for boxes and lighting. Designed by F. J. Rigney. As is so often the case the use of all capital letters for the captions makes reading difficult—especially with hand lettering. The unlighted captions suffer in contrast with the well-lighted scenes. Borrow a photograph of the exhibit to understand it fully.

"Just one thing at a time" is urged by Edith M. Ross in *Survey*:

Are most of us eye- or ear-minded? Do

we notice more, do we remember better, what we see or what we hear? From my own experience, first as a county nurse, then in state work, I find that people remember better what I say if they can see at the same time something allied to the subject of my talk. Charts, especially in speaking to adults, always help. Tack maps are nearly always fascinating. There is something concrete, vital about them—something that takes away the intangibility of mere figures and brings facts home to us. Our public is far more hungry for information than we imagine. But we must be careful not to repel it by trying to feed it dull, dry, lifeless facts.

The staff nurses of the Minnesota Public Health Association, when they make school inspections, use a small cloth dog or monkey or a "Felix" cat to arouse the interest of the younger children. Into any of these, which consist of a head and forelegs, we run the fingers of one hand. Then we get the children to ask it questions such as: "How many glasses of milk do you drink?" or "What time do you go to bed?" And the dog or cat or monkey, as the case may be, waves one paw slowly to indicate the number of glasses of milk he consumes or the hour at which he retires. He shows them, too, how he washes behind his ears, how he brushes his teeth. There are few health habits which these toy animals cannot help us expound. And when I return the following year, I find that what Coco, my monkey, or Milko, my dog, has told them has not been forgotten.

What and What of It?—What you are doing in broadcasting health material, and whatever evidence you have that audiences are listening in will be of great interest in a session at the National Conference of Social Work in June.

Please send copies of any typewritten or printed reports, with supplementary information. Especially wanted: *do you do anything beyond straight talks?* Please send now to editor of this department.

All of this material, and more, will be shown also at Montreal in September.

BOOKS AND REPORTS

Insects, Ticks, Mites and Venomous Animals of Medical and Veterinary Importance. Part II—Public Health—*By Walter Scott Patton, M.B., Ch.B., F.E.S. Dept. of Entomology, School of Tropical Medicine, Liverpool, England, 1931. 740 pp. Price, \$6.00.*

This volume is Part II of the series treating of the pests mentioned in the title, Part I being devoted to the medical, while this deals with the public health standpoint. The arrangement is in general the same, the successive chapters being arranged for the sessions of classes working for the diploma in public health, the whole course consisting of 9 meetings of 2 hours each.

During the first part of the meetings, brief explanations of the zoölogical nomenclature, classification, etc., are given, followed by laboratory work in which typical examples of the orders of insects discussed are exhibited. Short summaries of the material covered at each meeting are given, and a revision of the whole ends the part of the volume devoted to the course.

Two appendixes follow, the first of which describes the dissection of the alimentary tract and salivary glands of the mosquito, while the second, 340 pages in length, is devoted to the household arthropods and their control. This ends with lists of those which are destructive to household belongings, such as books, leather, carpets, tapestries, blankets, furniture, and woodwork; foodstuffs, such as stored grains and their products, spices, coffee, cacao beans, dried and fresh fruits, cheeses, cured and fresh meats, drugs, museum collections, etc. A section is given to those curious insects which damage lead.

There are innumerable illustrations and 57 plates, a number of which are in colors, and all of which are exquisitely done.

Our growing knowledge of the important part played by insects in the spread of disease and of their menace to our comfort as well as our food supplies gives this book an added value. No review can do full justice to it. It must be seen and studied.

The frontispiece is a photograph of Dr. Leland O. Howard, for many years Chief of the Bureau of Entomology of the U. S. Department of Agriculture, who is termed the "Father of Public Health Entomology." The legend pays him a well deserved tribute which will be appreciated by all Americans. Bound on the inside of the back cover is a chart giving the classification of arthropods of public health importance.

The printing and make-up of the book are excellent, and there are two good indexes, one to the part of the book devoted to the course and Appendix I, and the other to Appendix II. While designed for teaching purposes, this series contains an enormous amount of information which will be found most useful to physicians and public health workers. Appendix II will appeal to a wide range of students as well as to the general public. The price of the book is remarkably low. M. P. RAVENEL

Cancer and Scientific Research—*By Barbara Holmes, Ph.D. London: Sheldon Press, 1931. 160 pp. Price, \$1.50.*

Cancer is generally conceded to be one of the most serious of all public health problems. Despite the intensive educational efforts at cancer control

which have been directed at the laity, malignant diseases as a whole have not been diminished. Instead, there has been, in the opinion of many competent observers, a persistent increase in neoplastic diseases, although this now seems to be slowing down.

The wider the established knowledge about cancer, the better. Authoritative books of a popular nature on this subject are, however, unfortunately, rare. This little book is a worthwhile contribution to cancer literature because it presents an able digest and interpretation of a vast amount of experimental research of a highly technical nature.

Sanitarians who desire to add to their conception of the cancer problem will find this book of value. The style is pleasing and it is written, in general, with true scientific restraint, although some biologists may not agree wholly with the conclusions regarding the inheritance of cancer, which are based chiefly on the disputed work of Maude Slye. The highly intelligent lay reader will also find the book of interest, for as Sir F. Gowland Hopkins writes in a brief preface, "It is striking, indeed, to find how much enlightenment is given in so small a book."

JAMES A. TOBEY

Laboratory Diagnosis—By Edwin E. Osgood, M.A., M.D., and Howard D. Haskins, M.D. Philadelphia: Blakiston, 1931. 475 pp. Price, \$5.00.

As stated in the preface, the object of this book is "to teach the habits of thinking that are necessary to obtain the fullest information from laboratory sources." The authors are professors in the University of Oregon Medical School and the book is the outgrowth of their experiences in teaching and in the laboratories of the hospitals connected with the university.

The book is divided into two parts. Part one is primarily of interest to the practitioner and considers the knowl-

edge which he must have available at the bedside of the patient. At the beginning of each chapter a brief résumé is given of the essential anatomy, physiology, biochemistry and pathology and at the close of each, very useful tables of summaries and limits of laboratory findings to be expected in normal and pathological conditions are found. A special "index by diseases" of this part should be very useful.

The second part of the book is devoted to the details of laboratory procedures involved in the different methods recommended in Part I. Two short chapters are given to the Calibration of Apparatus and the Preparation of Standard Solutions.

The treatment of bacteriology and serology is admittedly very incomplete, consultation of textbooks on these subjects being recommended. In every case the methods which the authors prefer are emphasized and in many cases are the only ones given. The omission of all methods using Nessler's solution is striking.

Throughout there are generous footnote references to the original literature. Many useful tables which aid in calculation are given and the 6 colored plates in the chapter on Hematology are especially well done. The book is very well printed on good paper and is free from typographical errors. The unusual treatment of the material given, especially in Part I, should make the book interesting and useful both to the practicing physician and the laboratory worker.

A. B. HAW

Safety Education—Idabelle Stevenson. New York: A. S. Barnes & Co., 1931. Price, \$1.00.

There are several excellent books on safety and accident prevention, but this little volume by the Executive Secretary of the Education Division of the National Safety Council stands quite unique as representing the essentials of

Safety Education. It is evidently written by an expert who is offering to the "teacher-leader a program full of wholesome procedures that bring the full force of safety into the life of the individual pupil, the school group, and the community."

Ten short, tersely written chapters cover the problem, general methods of teaching safety, student safety organization, safety patrols, accident reporting and inspection, publicity, assembly programs, special projects, safety in the athletic program, and essential information in regard to street safety, safety in sports and recreations, and in the home.

Safety data, charts, axioms, "what-to-do's," and "how-to-do-it," and a list of junior safety councils, manufacturers of badges, etc., and a selected bibliography accompany. Safety consists in the correct way of doing things, but first there must be a correct way of thinking, which means proper training in childhood. Incidentally, the data show that accidents among children are decreasing while those among adults are decidedly increasing. Credit for this may justly go to the current child safety program. Teachers, parents and others will find this book of paramount value.

EMERY R. HAYHURST

What We Drink—By Various Authors, with Introduction by Sir James Crichton-Browne. Edited by Hugh Wansey Bayly. Issued under the Authority of The Scientific Committee of the True Temperance Association. London: William Heinemann, 1930. Price, \$.40.

Evidently written for lay people, this book will disappoint those who look for something more exact or extensive. The information is correct as far as it goes. Inasmuch as the great use of soft drinks is peculiarly American, this chapter particularly will fail to satisfy American readers. There is scant mention, for example, of the large number

of soft drinks in this country, which are all classed as "Coca-kola," which contain caffeine, but some five pages are given to a discussion of the English "public house system" in which foods as well as drinks are sold. In general, however, it will aid the public in the proper selection and control of beverages, and be an aid to temperance.

M. P. RAVENEL

Food Poisoning and Food-Borne Infection—By Edwin Oakes Jordan. Chicago: University of Chicago Press, 1931. 286 pp. Price, \$2.50.

This book, belonging to the University of Chicago Science Series, supplants *Food Poisoning* by the same author, issued in 1917. Since that time, poisoning by foods has been intensively studied, particularly in England and America. The packers themselves were among the first to recognize the necessity of this, and have appropriated liberally for investigations carried on at the Universities of California, Chicago, Harvard, and Stanford. The author played an active part in some of the most important of these, and is peculiarly well fitted to write on the subject. He has put the sum of available knowledge into a small space, but has covered the necessary points in satisfactory fashion.

We consider the section on Spoiled and Decomposed Foods, short as it is, of more than usual interest, perhaps because it discusses matters which are not so often considered as the well known and too often occurring acute outbreaks. Certainly this matter needs further study. In view of the "imperfect and unsatisfactory" state of our knowledge, we commend the opinion expressed that we must continue our methods of protection.

The printing and make-up of the book are good, the illustrations fairly so. Good indexes of authors and subjects end the volume.

M. P. RAVENEL

Lateral Curvature of the Spine and Round Shoulders—By *Robert W. Lovett, M.D.* (5th ed.) Revised and edited by *Frank E. Ober and A. H. Brewster*. Philadelphia: Blakiston, 1931. 240 pp. Price, \$3.50.

The fifth edition of Lovett's *Lateral Curvature of the Spine and Round Shoulders* adds to this classical treatise the results of modern experience. The 24 years that have elapsed since the first edition have produced nothing to controvert the admirable research of Dr. Lovett, upon which have been based the principles of treatment since that time. It is along lines of treatment itself that changes and additions to the original edition have been found necessary. Both the new material and the reorganization of the old render the present edition of vastly greater value to the practitioner.

The revamping of the section on exercises has been particularly successful, and the clarity of both pictures and text renders that part of the work of inestimable value. This may also be said of the chapters on supporting and corrective devices. The ingenuity and effectiveness of the turnbuckle jacket are strikingly brought out both in the photographs and roentgenograms.

By no means the least of its values is the brevity and compactness of the book. Aside from its scientific worth, it is indispensable as a working manual for every orthopedist, and will be a most useful guide to those interested in the preventive aspects of child culture.

KENDALL EMERSON

Determination of the Interrelations, Partial and Multiple, Between Various Anthropometric Measurements of College Women—By *Mary Louise Boillin*. Teachers College, Columbia University: Bureau of Publications, 1930. 63 pp. Price, \$1.50.

A study of college women is described

wherein data are collected from which the correlations of body weight with various anthropometric magnitudes are obtained. The questionable assumption that body weight, properly chosen, is a fundamental index to health even at maturity seems to underlie the point of view. Height is not as reliable in determining weight expectancy as has been believed, other skeletal dimensions having more value. In late adolescence, weight may have some real diagnostic value in determining the degree of health.

ALLEN E. STEARN

Facts and Figures About Tuberculosis—Compiled by *Jessamine S. Whitney*. New York: New York Tuberculosis and Health Association, Inc., 1931. 63 pp. Paper. Price, \$.75.

Miss Whitney's monograph, *Facts and Figures About Tuberculosis*, will fill a real want.

To student and teacher in need of up-to-date facts on the important aspects of tuberculosis, it will be invaluable. Concisely and clearly, Miss Whitney has delved into and makes available here measured knowledge of the mortality rates from tuberculosis in the entire United States for a whole generation; the differences by sex and by color in different sections; the mortality percentage in important occupational groups; figures of geographical distribution; relation to other important causes of death; nationality rates, comparative death rates in various parts of the world; data on institutional facilities, clinic, sanatorium and nursing. Particularly informative also is the unusual chapter on tuberculous infection and the percentages of reaction found by various investigators in different communities.

In the United States, next to widespread general education, it has been well remarked that public health progress has been the most distinctive achievement of the American democ-

racy; and the measures for the control of tuberculosis have been one of the leading parts in this. To the social student, Miss Whitney's measured statements on the prevalence and gradual diminution of tuberculosis in the United States offer a rare mine of contemporaneous historical facts to be studied readily here. To the public or private health official charged or connected with tuberculosis responsibilities, the information should be most helpful in organizing his work more understandingly.

G. J. DROLET

Health Field in Social Work, From "Proceedings of the National Conference of Social Work," 1930.

One seldom picks up a volume of convention proceedings whose table of contents offers so many names of national prominence and authority in as many fields as the volume made up of selected papers presented at the 1930 Conference of Social Work in Boston. In the presidential address of Dr. Miriam Van Waters one reviews the six decades of progress since 1874 when the first "Proceedings" was published and he finds that "we do not solve our problems by the techniques we evolve; we merely outlive them"; that the same problems confront the worker today as in 1874, but that the decades have brought a philosophy of understanding life which gives to those who practise it the ability to face life realistically, as it is, and as it may be, without dogma or fear.

George W. Wickersham's very enlightening address on law enforcement urges education and persuasion in law observance to supply what the authority of church and home now fails to provide.

Several outstanding papers from the health section are included. The first of these, "The Chronic Disease Problem in Massachusetts," by Dr. Herbert L. Lombard outlines very extensive studies

in the control of chronic disease in the middle-aged. The five variables which have significance in the problem are age, sex, economic status, density of population, and nationality. Additional data are being collected in regard to life habits to determine importance of such factors as diet, emotions, rest and relaxation, and environment.

Since the Massachusetts Department of Health has developed one of the most extensive state-wide programs for cancer, Dr. G. H. Bigelow's paper, "The Massachusetts Cancer Program," is of utmost significance and interest. Dr. C.-E. A. Winslow's very interesting paper on "The Health Survey as a Social Instrument" gives a practical and conservative discussion of the value of the health survey as an instrument of measurement and standardization, but with the warning that while a mathematical formula applies to all cases in its entirety, a form of social organization does not; so that a successful survey must recognize community characteristics and combine outside expert knowledge with local experience.

Wesley C. Mitchell's paper, "The Economic Basis for Social Progress," brings out the significant fact that the average earnings of \$1,205 or \$1,304 should no longer be compared with the minimum family budget of \$2,057 or \$2,100, for the average family has 1.8 gainful workers including young and old people. HOWARD WHIPPLE GREEN

Dental Health—By George A. Swendiman. Boston: Stratford Co., 1930. 121 pp. Price, \$3.00.

Chapter I on habits is good advice for the layman. We cannot agree with all the ideas expressed in Chapter II on the temporary teeth. Experience and research are changing some of the old accepted viewpoints expressed by the author.

Chapter IV presents clearly a true statement regarding the cleaning of

teeth which should be understood by all laymen. Chapter V presents the focal infection idea in the light of the most recent researches, which is the best viewpoint the profession has today. It seems most improbable that we will change the viewpoint that non-vital teeth are always a menace to their host.

Chapter VI on pyorrhea is a sane statement with good advice for the layman. Chapter VII on oral hygiene presents some questionable methods but it is hard for men to agree about something that is not based on true research. We doubt whether the method of brushing the teeth makes very much difference just so we keep the teeth reasonably clean.

Chapter VIII gives the layman many true and valuable points about dentistry that should help him to select the type of service he desires. Chapter IX presents good points on the social side of dental health but we fear the writer has not really met the social problems in any large way. His attitude is good, but his experience with the problems of social dental needs appears limited.

On the whole, the book is good. It is well written, clear and simple in explanation, that is, it is as simple as it is possible to make a highly technical subject.

The book covers the field in a way not covered by any other book with which I am acquainted.

It can be honestly recommended as an excellent book for the layman.

HARRIS R. C. WILSON

Civilization and the Cripple—By Frederick Watson. Bale, Sons & Daniellson, Ltd., 1930. International Society for Crippled Children, Inc., Elyria, O. Price 10/6 net, \$2.50.

This is an excellent presentation of the cripple and his relation to society. Included under the term "cripple" are all industrial and other accidents as well as conditions resulting from disease and

congenital defects in adults and children.

Mr. Watson speaks from a long familiarity with his subject. He founded and has edited for more than five years the international quarterly journal *The Cripple*. He has also had experience in organization as county director of the British Red Cross Society and chairman of the Montgomeryshire Voluntary Orthopedic Association, and experience in rehabilitation as deputy controller in the Appointments Department of the Ministry of Labor during the demobilization period after the Armistice.

The book as a whole is extremely interesting. An historical review of the cripple from antiquity down to 1930 is given. It was not until the 18th century that experience and reason came into play. The first Factory Act in England was in 1802, though already the great English, French and German bone and joint surgeons had done notable work, and in America, Dr. John Ball (1789–1862) opened his hospital for cripples. John Little (1810–1894) was the first great apostle of orthopedic surgery in England. The great influence of the war, the rapid development of orthopedics as a speciality, and the focusing of attention on the crippling conditions in soldiers, are well discussed.

It is interesting to note the progress which has been made in this country and the emphasis placed on it by Mr. Watson in the chapter entitled "The American Scheme." The chapter on "Prevention and Rehabilitation" is forcefully written and contains many excellent suggestions for the solution of the problem. The book is well written and presented in a most orderly fashion, and is of vital interest to any one associated or interested in the problem of "The Cripple."

The printing, illustrations and make-up are excellent. The book can be recommended without reserve.

G. KENNETH COONSE

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Manchester, N. H.—The 1930 printed report of this city of 76,834 population records a death rate of 11.0, a birth rate of 16.9, an infant mortality rate of 67, and a tuberculosis death rate of 35. In the tuberculosis clinic there was an attendance of 798, 222 new patients being examined. A total of 1,561 home nursing visits was made by the clinic nurse.

In the administration of the school health program, the schools have been divided into 3 districts with a physician and 2 nurses assigned to each district. Children in the kindergarten, first, fourth, and eighth grades are examined annually. Children in the kindergarten and first two grades, whose parents so request in writing, are given toxin-antitoxin by the school physician. Weekly clinics for giving the treatment to preschool children and others who wish it are held at the office of the health department.

Newport, R. I.—This city, with a population of 27,430, including 1,926 persons of the U. S. Army and Navy, reports 456 births and 353 local deaths, and an infant mortality rate of 37.28. Four cases of diphtheria occurred with no deaths. Since 1923, 3,312 children have been immunized, including 47 per cent of the school population. The health department expenditures amounted to \$.86 per capita. According to the 1930 report, for 12 years there has been enforced an ordinance permitting the sale of only milk of pasteurized or certified grades.

Maryland—An analysis of 84 typhoid fever carriers listed in the office of the State Department of Health shows that 256 cases of the disease were traced to these sources. By occupation,

39 per cent were housewives, 11.9 per cent milk handlers, 9.5 per cent cooks, 2.4 per cent laborers, 7.1 per cent farmers, 4.8 per cent shell fish handlers, 9.5 per cent school age children, and of 17.8 per cent occupation was not stated. By bacteriological examination, 48.7 per cent were found to be stool carriers, 9.5 per cent urine carriers, 15.5 per cent stool and urine carriers, 26.3 per cent not stated. A definite history of previous typhoid or paratyphoid was stated in 69 per cent of the carriers.

During the year the Bureau of Child Hygiene conducted 420 conferences at which 6,791 children were examined and referred to their physicians. Prenatal conferences were continued. Ten orthopedic conferences were conducted in the counties by representatives of the League for Crippled Children in cooperation with the bureau. Courses in midwifery were offered in several counties, and only those midwives were licensed who attended these classes or had received corresponding instruction. An important survey of maternal deaths in the state was completed and preliminary figures are presented in the annual report. Negro health week was observed and a colored physician representing the bureau conducted child health conferences for negro children in several counties of the state.

Knoxville, Tenn.—The 1930 annual report, in mimeographed form, outlines the work carried on by the bureau of health and contains excellent tabular and graphic material of interest in illustrating the descriptive text. Certain low records were established, including infant mortality (70), typhoid (1.8), diphtheria (2.8) and tuberculosis (69). Expenditures amounted to \$104,941 in this city of 107,200 population

The work of the division of general sanitation is organized on a district basis, there being 6 districts. Of the total nuisances abated, it is noteworthy that 96 per cent were found by the inspectors on routine premise to premise inspection, while 4 per cent of the corrections resulted from complaints. There were 2,966 sanitary sewer connections effected during the year. Milk control is exercised in accordance with the standard milk ordinance of the U. S. Public Health Service.

Orange County, Calif.—This county of 800 square miles, with a 1930 population of 118,611, even distribution of population, and good roads, is well adapted to the county unit plan of health administration. According to the annual report, 12 incorporated cities have contracted with the county health department for central health administration. The largest city, Santa Ana, has a population of 30,332 and is centrally located. The recording of vital statistics was transferred to the health department during the year. Another advance step was the completion of arrangements in two communities whereby the school districts and the county shared the expenses of the public health nurses, so that in each of these localities the one health worker carried on a generalized program.

During 1930, 2,130 individuals were given 3 immunizing doses against diphtheria. There were 164 cases and 3 deaths from this disease. There were 2,375 smallpox vaccinations performed.

The health promotion program for the infant and preschool child takes the form of mothers' educational centers, 358 conferences having been held during 9 months of 1930, with an attendance of 4,572, 562 visits being made by Mexicans. Home visits in the interest of child hygiene numbered 1,123. A weekly bulletin is sent by the health department to all physicians and health

workers in the county, stating the presence of communicable disease and containing suggestions regarding health work. The year's budget amounted to \$66,727.

Palama Settlement—Palama Settlement is a health and welfare center in Honolulu where a fourfold program of medical, dental, nursing and recreation services is provided. This is the chief voluntary health organization in the city. The 1930 annual report is one of the most attractive and comprehensive reports of the year.

More than 12,000 families received care last year, and through the recreation department some 10,000 individuals were helped toward better citizenship. In the field of public health nursing, a generalized city service has been developed through a pooling of the nurses of Palama and of the Board of Health. An average of 115 poor sick patients are seen daily by the medical staff. Preventive dental treatment provided for 4,133 first and second grade school children last year. Thirteen well baby and preschool conferences were regularly held. Two health building summer camps for undernourished boys and girls were maintained. Health education was highly developed through talks, radio, motion pictures, exhibits, articles, and activities to advance the health knowledge of the community. Boys were taught leadership and responsibility in clubs and through athletics. Girls were taught home-making, swimming, dancing, camping, and participated in athletics. Staff members served on 18 major health and welfare committees of the city. Expenditures amounted to \$194,503.

During the year, the nurses assisted in immunizing 7,753 preschool and 331 school children against diphtheria, and in the health examination and vaccination of 5,510 preschool children. There were 962 medical examinations of foot-

ball and basketball players. Exclusive of 1,712 prenatal clinic visits, there were 35,919 visits to the medical department by individuals representing over 13 racial groups, the Japanese, Porto Rican, Portuguese, Korean, Hawaiian, and Filipino races predominating. X-ray examinations numbered 2,138. Over 50 per cent of the preschool children in the city have been protected from diphtheria by immunization and over 65 per cent have received health examinations.

San Jose, Calif.—The 1930 report indicates for this city of 57,651 population a birth rate of 14.1, a death rate of 10.8 and an infant mortality rate of 45.7. Of the 588 births, 72.6 per cent

occurred in hospitals. Excellent graphs illustrate the statistical report. There were 515 children immunized by the health department with toxoid and 533 vaccinated against smallpox. Two new milk pasteurizing plants were built during the year, making a total of 9 in operation in the city.

Activities in popular health instruction include monthly bulletins to the city council, press, physicians, schools, and health workers, besides an annual report and in addition to the use of various health pamphlets furnished by insurance companies.

The attractiveness of the report is increased by the use of several photographs.

BOOKS RECEIVED

INSECTS, TICKS, MITES AND VENOMOUS ANIMALS OF MEDICAL AND VETERINARY IMPORTANCE. Part 2. By W. S. Patton. Liverpool: School of Tropical Medicine, 1930. 740 pp. Price, \$6.00.

PROTOZOAN PARASITISM OF THE ALIMENTARY TRACT. By Kenneth M. Lynch. New York: Macmillan, 1930. 258 pp. Price, \$3.75.

THE CRIMINAL, THE JUDGE, AND THE PUBLIC. By Franz Alexander. New York: Macmillan, 1931. 238 pp. Price, \$2.50.

AMERICAN STANDARDS AND PLANES OF LIVING. By Thomas D. Eliot. Boston: Ginn, 1931. 931 pp. Price, \$5.00.

HEALTH AT THE GATEWAY. Problems and International Obligations of a Seaport City. By E. W. Hope. New York: Macmillan, 1931. 213 pp. Price, \$5.00.

MEDICAL ADMINISTRATION OF TEACHING HOSPITALS. By Emmet B. Bay. Chicago: University of Chicago Press, 1931. 136 pp. Price, \$2.00.

NEWS FROM THE FIELD

ENTOMOLOGY LABORATORY MOVES

THE U. S. Department of Agriculture, Bureau of Entomology, Division of Insects Relating to Man and Animals, has moved its laboratory, formerly conducted at Mound, La., under Dr. W. V. King, to Orlando, Fla., with G. H. Bradley in charge.

ADVISERS ARE NAMED FOR NUTRITION STUDY

TWO Educators Appointed to Aid Government Research—L. B. Mendel, professor of physiological chemistry at Yale University, and E. B. Hart, professor of agricultural chemistry at the University of Wisconsin, two internationally known authorities on protein, vitamins and nutrition, have accepted appointment by the Department of Agriculture as advisers to its Protein and Nutrition Division in the Bureau of Chemistry and Soils.

The department called upon these authorities for their advice and suggestions as to how its work on nutrition may be improved, and to assist the staff of the Protein and Nutrition Division in strengthening the important lines of work now under way.—*U. S. Daily*, Apr. 24, 1931.

DR. HARRIS

DR. LOUIS I. HARRIS has severed his connection with the National Dairy Products Corporation, and for the time being is devoting himself to writing. He stated that he expects to remain in retirement until he finds a type of consultation work in public health administration or other public health work which will be congenial.

Dr. Harris entered the Department of Health of the City of New York in 1907 as a civil service employee and continued in that service in a variety of capacities, organizing the Division of Industrial Hygiene in 1914 and directing its work until he became Director of the Bureau of Preventable Diseases in 1917. In 1926, Mayor Walker selected him from a list of public health workers nominated by the New York Academy of Medicine, and he served for nearly three years as Commissioner of Health of the City of New York.

He has been active in the affairs of the American Public Health Association. He served as Chairman of the Health Officers Section, as a member of the Governing Council, member of the Executive Board, and as First Vice-President of the Association in 1930. He was Chairman of the Committee on Cooperation, Development and Finance, which formulated the plans and policies which the Association is now following.

HOSPITAL CARE FOR MENTAL PATIENTS

THE National Committee for Mental Hygiene, Inc., of New York, sent questionnaires to some 600 hospitals, asking for information as to the existence of clinics and psychopathic wards or departments where examination or treatment might be given to mental patients.

Of the 421 hospitals that replied, 122 reported special facilities; 17 reported incidental services; and a total of 3,298 beds for mental patients was reported by 53 of the 56 hospitals that have special wards.

Of the 122 hospitals that reported special facilities for mental patients, 56

have special mental wards; 97 reported clinics; 31 reported both wards and clinics; 25 reported wards only; and 66 reported clinics only.

THE ARIZONA PUBLIC HEALTH ASSOCIATION MEETING

THE Arizona Public Health Association held its fourth annual meeting at Nogales May 5 and 6.

WESTINGHOUSE AWARD

DR. C. M. SLACK, Research Engineer of the Westinghouse Lamp Company, recently received the "Award for Outstanding Accomplishments" and the accompanying \$500 in cash for the development of a glass bubble to be used as a window in the Lenard Ray Tube. This award is given each year by the Westinghouse organization for the most important changes either in

manufacturing methods or the design of a product made by the company. Lenard Ray Tubes are used to produce high speed electrons or Lenard Rays outside the generating tube for experiments in the field of chemistry, biology, and luminescence.

SIGHT-SAVING CLASSES THIS SUMMER

FOUR universities will offer courses for the training of teachers and supervisors of sight-saving classes this summer. The courses will be as follows:

Tulane University, New Orleans, La.,
June 15 to July 24
University of Chicago, Chicago, Ill.,
June 22 to July 24
State Teachers College, Buffalo, N. Y.,
June 29 to August 7
Teachers College, Columbia University,
New York, July 6 to August 14

PERSONALS

FRANCIS E. FRONCZAK, M.D., F.A.P.H.A., attended the meeting, May 19 to 24, of the Royal Institute of Public Health in Frankfurt-am-Main, as an official representative of the A. P. H. A. In the same capacity he will attend the International Hospital Congress in Vienna and Budapest, June 8 to 14.

ALFRED F. HESS, M.D., pediatrician, member A. P. H. A., was elected one of the new members of the American Philosophical Society at its meeting in Philadelphia on April 24, 1931.

H. T. G. NAUMANN, City Chemist of Port Huron, Mich., member A. P. H. A. since 1917, died January 30, 1931.

JANE H. RIDER, State Sanitary Engineer, Tucson, Ariz., was recently elected an associate member of the American Society of Civil Engineers. This signal honor has been awarded

to only one other woman in the United States.

HENRY A. ROWLAND, for the past 16 years Secretary of the Department of Public Health of Toronto, Ont., Canada, and member A. P. H. A., has been appointed Superintendent of the Riverdale Isolation Hospital, at Toronto.

EDGAR B. KAY, of Washington, D. C., member A. P. H. A., former dean of the School of Engineering of the University of Alabama and former chief of the Hydraulic and Sanitary Division, Quartermaster's Office, U. S. A., died April 20, 1931.

DR. JOHN A. WESSINGER, of Ann Arbor, Mich., has just been re-appointed City Health Officer for a term of 3 years, this being his ninth re-appointment, Dr. Wessinger having served 24 years up to the present time.

CONFERENCES

- June 8-12, The American Medical Association, Philadelphia, Pa.
 June 14-20, National Conference of Social Work, Minneapolis, Minn.
 June 15-20, First National Conference of the American Association of Public Welfare Officials, Minneapolis, Minn.
 June 18-19, Pennsylvania Public Health Association, Harrisburg, Pa.
 June 22-27, American Home Economics Association, Detroit, Mich.
 June 23-24, Fifth Annual Conference of the Pennsylvania Sewage Works Association, State College, Pa.
 June 27-July 4, National Education Association, Los Angeles, Calif.
 June 28-July 3, Second World Conference on Crippled Children, The Hague, The Netherlands.
 June 29-July 1, New York State Con-

ference of Health Officers and Public Health Nurses, Saratoga Springs, N. Y.

July 27-August 2, The World Federation of Education Associations, Denver, Colo.

July 26-31, Third Congress of the Pan American Medical Association, held under the auspices of the Mexican Government, City of Mexico, Mexico.

September 14-17, Sixtieth Annual Meeting, American Public Health Association, Montreal, Canada.

A new era in handkerchief hygiene!

KLEENEX

DISPOSABLE TISSUES

Use once and discard—avoiding self-infection from germ-filled handkerchiefs

WE MODERNS PREFER

electric lights to old oil lamps and motor cars to the horse and rig of an earlier age because we get results more quickly and more efficiently.

AGAROL is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

Similarly in constipation—a modern day has developed a modern way—AGAROL. To meet every modern need, Agarol combines efficiency with palatability. No oily taste, no artificial flavoring to get used to.

Effectiveness must be experienced.

A supply gladly sent for trial.

Iodine in Nutrition*

WILLIAM WESTON, M. D., DR. P. H.

South Carolina Food Research Commission, Columbia, S. C.

FOR more than 25 centuries it has been known that there was something in certain marine products that exercised a specific influence upon the thyroid gland. The Chinese, Phoenicians, Greeks, Romans and other peoples who had acquired an advanced degree of civilization all appear to have been in possession of this information. It was not known until Davy discovered it in 1815, that the efficacy of burnt sponges and other marine products was due to the presence of iodine, an element discovered by Courtois in 1811. In 1820 Coindet, a physician in Geneva, suggested that the beneficial effect on goiter of these marine products might be due to the iodine they contained. He conducted experiments upon goiter patients by administering tincture of iodine, with the result that the goiters disappeared. He observed, however, that certain of these patients manifested toxic symptoms and consequently he concluded that this method of treatment should be closely supervised. Among those who were investigating the treatment of goiter about this time and by whom its dangers had been observed was d'Espine, who estimated that the minimum curative dose was 0.5 mg. per day.

During this period the subject was studied from several different points of view and considerable information was accumulated that suggested the connection between iodine deficiency and goiter. Angeline in 1824, and Cantu in 1825, found iodine in certain springs which had a reputation for the cure of goiter. A few years later Boussingault observed that the sea salt of Gauca exercised a decidedly beneficial influence in the prevention of goiter in the people of the Andes where goiter was very common.

* Read before the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

In 1849 Prévost suggested that goiter was due to a deficiency of iodine and bromine in drinking water. He suggested that when iodine was present in salt it gave protection against goiter.

Between 1850 and 1854 Professor Chatin of Paris made very extensive investigations. Following these he announced that where the soils and waters were relatively high in iodine goiter was unusual, but when low in their iodine content many cases of goiter and cretinism were observed. Chatin's views were severely criticized for a period covering several years, but his basic observations have become so firmly established and have been so often confirmed, both in Europe and this country, that we may safely conclude that they are correct. Among those who have studied Chatin's observations is McClendon of the University of Minnesota. His investigations were most extensive and agree in practically every detail with Chatin's findings.

Among others whose investigations led to definite conclusions was Lombroso, who recommended that all marriageable individuals residing in goiter areas should be treated with iodine for the prevention of cretinism. I believe it was he who first recommended the use of iodine in the treatment of farm animals in goiter areas, a measure that has been largely adopted and which has resulted in saving from ruin the live stock industries in those areas.

Probably the first to suggest the use of iodine in salt as a routine measure of treatment in the prevention and cure of goiter was Koestl, who in 1855 began its use in Austria.

In practically all of the goiter areas of Europe there occurred a wave of enthusiasm for the use of some form of inorganic iodine in the treatment and prevention of goiter. It appears that a most indiscriminate use of the various iodine preparations was indulged in with many instances of poisoning.

It was not until 1860 when Rilliet presented to the French Academy of Medicine a classical description of the toxic symptoms which follow over-dosage of iodine that medical men began seriously to consider their error. Following the widespread circulation of Rilliet's report the administration of so-called inorganic iodine began to be considered by many as dangerous and by others as either impractical or ineffective. It may be pertinent to mention here that so thoroughly did Rilliet consider his subject that although it was presented 70 years ago, no one since has presented nearly so comprehensive a report. It would be well if each physician residing in the vast goiter area of this country would familiarize himself with it.

Iodine is widely distributed in nature but is present in small and variable quantities in both organic and inorganic substances. The

air, water, soils, rocks, mineral ores and marine products have for many years been considered the most important sources of iodine. Within the last few years McClendon¹ has called attention to vegetables grown in certain sections as being of great value in the prevention and treatment of goiter. In the past 2 years Remington² has analyzed hundreds of samples of vegetables and as a result of his work the subject has been greatly advanced.

The amount of iodine in the air is extremely variable. Gautier³ found approximately 16 times as much iodine in the air at the seashore as in Paris. However, von Fellenberg found that the amount of iodine in the air varies greatly in the same locality and is subject to such influences as rain, dews, altitude, and the presence of large amounts of soot.

The amount of iodine present in drinking waters is, generally speaking, of little consequence when considered in its individual relationship as a reliable source to supply the bodily requirements. However, certain springs in France and Austria are said to contain a sufficient amount of iodine to prevent goiter. Investigators, both in this country and Europe, report a very much greater amount in the water from the non-goitrous areas than in those where the goiter incidence is high. McClendon¹ found that drinking water in the lower Mississippi Valley contains 100 to 1,000 times more iodine than that in the basin of the Great Lakes. In the former district there is practically no goiter, while in the latter from 35 to 60 per cent of the children are so afflicted. Chatin estimated the amount of iodine in 300 rivers. Perhaps his most important conclusion was that water from sources rich in lime and magnesium and from melting glaciers are invariably low in iodine.

Hercus, Benson and Carter⁴ analyzed the water from 3 New Zealand rivers with the following results: the Clutha was iodine free, the Taiere contained 1 microgram and the Leith 2 micrograms per liter.

Mitchell⁵ found a wide variation in the iodine content of the different rivers in South Carolina. In the Seneca River he found 1.86 parts per billion and in the Broad 6.53 parts per billion. It is interesting to note that water taken from these rivers and subjected to treatment by chemicals and filtration resulted in a loss of iodine of from 30 to 70 per cent.

Sea water from the several oceans has been analyzed by von Fellenberg, Blyer, Heymann, McClendon and others. These waters show remarkable variation which cannot be accounted for by differences of method, because von Fellenberg⁷ found that the water from the Mediterranean contained 17 micrograms per liter, while that at

Biarritz contained 57 micrograms per liter. Although seaweed and plankton concentrate enormous amounts of iodine, the opinion which prevails that the sea is our chief source of iodine is fallacious. Soils in many places contain a greater amount of iodine than does the sea. The richest deposits are in Chile.

Iodine is present in the various metal ores and is relatively rich in some of the copper and iron ores. It does not, however, appear to have any special affinity for any metal.

OCCURRENCE OF IODINE IN THE BODY

It is difficult to state in exact terms the total quantity of iodine found in the body ash, because of certain influences, such as locality, sex, age and season. A much greater amount is found in those residing in non-goitrous areas than in those where goiter is common.

Age⁸ also seems to exercise an important influence. At birth practically no iodine is found in the thyroid gland and after the first 3 or 4 months the quantity seems to increase up to puberty. There is a slightly greater amount in the bodies of women than men, and a number of authors have noted a marked seasonal variation in this country.

The total quantity of iodine in the body of the average adult has been variously estimated by Lunde, Class,⁹ Wulfert, Justus, Sturm, von Fellenberg and others. On the average of these we may estimate it at 51 mg. Of this 25 mg. are in the musculature, 10 mg. in the thyroid, and the remainder in small proportions in the spleen, suprarenals, salivary glands, the bones, skin and blood. Certain American investigators report that the thyroid gland contains almost half of the total body iodine. This matter is largely or entirely determined by the iodine content of the diet.

IODINE REQUIREMENT

Since 1896 when the German chemist Baumann discovered the presence of iodine in the normal thyroid gland, much work has been done by chemists in Europe and America to determine the actual amount required by the body. We must remember that iodine is in constant circulation in the blood and that we have a normal iodine metabolism.

Lunde and Class¹⁰ estimate the normal iodine concentration of the blood at 11 to 16 micrograms per 100 c.c. They estimate the amount necessary to meet all requirements of metabolism at around 0.05 mg. per day. In the presence of some infection or some increased physiological activity such as puberty, pregnancy, lactation or the menopause, a greater amount is required. A simple calculation will demon-

strate this, if taken in its organic relation, to be excessive, i.e., beyond nutritional requirement. It is my opinion that less than one-tenth of this amount is more than sufficient to prevent or cure incipient endemic goiter. It is also true that people living in areas where the diet supplies an adequate amount of iodine have smaller thyroid glands, but these contain a greater amount of iodine than those of people living in areas where the glands are larger.

IODINE IN NUTRITION

Concerning the physiological functions of iodine in nutrition—(1) Iodine furnishes the most important element which enables the thyroid gland to synthesize thyroxin. The thyroid gland contains 65 per cent of iodine. Thyroxin is the hormone which regulates the basal metabolic rate and determines the rate of function of all the glands in the body. (2) A sufficient amount of iodine in the diet of the mother increases the weight and growth of the young. It also makes the young strong and more apt to survive. (3) The iodine content of the ovaries and uterus is fairly high, especially when the diet is abundant in this element. When this is the case reproduction is favorably influenced. (4) A deficiency of iodine in the diet results in enlargement of the thyroid gland—goiter. (5) A deficiency of iodine in the diet results in frigidity, sterility and frequent miscarriage. (6) A lack of iodine extending over several generations gives rise to the birth of cretins, feeble-minded children and congenital idiots, and in adults myxedema.

Lunde in Norway¹¹ and von Fellenberg in Switzerland, have independently undertaken studies to determine an accurate method of measuring the daily iodine intake. Both investigators assume that

TABLE I

<i>School District</i>	<i>Percentage of goiter among school children (J. Nicolaysen)</i>	<i>Micrograms Iodine in 24 hours (G. Lunde)</i>
Hostvedt	59.7	40
Hvittingfoss	55.0	48
Ljsterud	54.0	29
Meheia	53.6	39
Saggrenda	43.0	64
Komnes	39.7	48

Eftett	36.6	65
Verp	36.0	87
Ruud	30.0	61
Vik i Sogn	0.0	173

¹¹ 1 microgram equals 0.001 mg.

regardless of where one resides he is in iodine equilibrium. They both found that approximately 60 per cent of the iodine intake was excreted in the urine. These experiments were conducted in high and low goiter areas and in those who had developed goiters and those who had not. Their results appear to be uniform and accurate (Table I).

I give von Fellenberg's figures for 3 Swiss provinces and for Forte dei Marmi on the Ligurian coast for the entire population (Table II).

TABLE II

	<i>Percentage of goiter</i>	<i>Micrograms Iodine per 24 hours</i>
Effingen	1.0	70
Kaisten	61.6	17
Hunzenschwil	56.2	18
Forte dei Marmi	0.0	112

Among the most important factors that seem to interfere with the utilization of iodine in the system are a high fat or protein diet or both. Kendall¹² of Rochester, Minn., finds that of the total iodine of the thyroid gland 60 per cent is in the form of diiodo tyrosine, 16 per cent as thyroxine, and there is no inorganic iodine. This finding is significant and is in harmony with the increasing conviction of investigators that none of the chemical elements exercise an absolutely independent action. It is probable that elements other than iodine are concerned with it in the production of those manifestations that have heretofore been ascribed to iodine alone. In their work on nutritional anemia Myers and Beard¹³ report that though copper supplements iron in hemoglobin regeneration, several other metals, among them germanium, arsenic, manganese and nickel, exercise a like influence.

There is constantly accumulating evidence that the inorganic form is not the method of supplying the necessary iodine, because it is of doubtful efficacy and apparently impractical. Resurveys following the use of iodized salt in Michigan for a period of several years have not shown the expected decrease in the incidence of goiter. The addition of iodine to drinking water has also proved disappointing."

After a most diligent and careful search of the literature I have failed to find a single incidence of iodine poisoning where the diet contains an enormous amount of iodine in its organic state. Perhaps Lunde is correct in his explanation. He writes:

Investigations have shown that when inorganic iodine is supplied it leaves the body quantitatively in a rather short time (less than 24 hours), mostly through the kidneys. The organically bound iodine of foodstuffs, however, is set free only

slowly in the organism, and a longer time elapses before it leaves the body. The question of the form in which iodine is utilized in the organism has not yet been solved; it is not known whether the organic compounds are first broken down so that the iodine can be disseminated in ionized form, or whether they are utilized directly. In any case it seems reasonable to assume that organic iodine compounds play an important part in the organism, since they are present in all tissues. A number of investigators have therefore emphasized the great importance of naturally bound iodine in goiter prophylaxis instead of the inorganic form.

Sufficient work has been done in the analyses of the various foods in the United States from which to select a diet that contains all the iodine that the body can utilize. It has been shown that sea fish contain a large though variable amount. The lean fish such as haddock, cod, coal fish and halibut has a high iodine content; herring and salmon may be considered as examples of fat fish and these have a much lower content. The shell and crustaceous fish possess a much higher iodine content than any other species, though, like other varieties, they differ tremendously.

The iodine content depends upon the available food supply. In some localities it is abundant, and in others scarce; consequently we find oysters that contain only 6,000 or 7,000 parts per billion, while others will range from 15,000 to 16,000.³⁵ Lunde³⁶ analyzed the oysters from Oslo Fjord and found that they had an unusually high iodine content. In that locality the plankton, which has the ability of concentrating an enormous amount of iodine, and upon which the oysters feed, was most abundant.

Clark³⁷ determined the iodine content of certain fish along the Massachusetts coast with the following results: soft shell clams 1,152 parts per billion, quahaugs 205, and cod 1,056. Remington³⁸ found that oysters from near Charleston contained 15,799 parts per billion.

As a result of a great number of analyses made by both McClendon and Remington³⁹ we are enabled to select vegetables, either canned or fresh, that contain relatively enormous amounts of iodine. The latter found spinach grown in South Carolina that contained from 800 to 1,200 parts per billion on the dry basis, and lettuce of like value; also that beans, asparagus, carrots, and other vegetables grown in the same state were extremely rich in iodine.

It is the feeling of pediatricians in an extensive section of the country that goiter is distinctly on the increase in young children. This observation suggested the importance of analyzing the available milk supply; consequently we undertook the task at the South Carolina Food Research Laboratory, in collaboration with Dr. McClendon of the University of Minnesota. When the results are considered the explanation becomes plain.

We are conducting experiments in order to determine whether spinach or lettuce when reduced to a concentrate and added to the milk formula in small quantities will not overcome the iodine, iron and other mineral deficiencies. The analysis of the spinach" being used is as follows: iron 543; manganese 140; copper 15; and iodine 840 parts per billion.

The lettuce" contains, approximately, iron 4,000 parts per million and iodine 900 parts per billion. Results are so far most gratifying.

Scharrer and Schwaibold" attempted to find out the form in which iodine is combined in milk. They separated the curd from the whey in normal goat milk. No iodine, or only traces, were found in the curd. Even when the animal was fed iodides, less than 1 per cent of the iodine of the milk was in the curd. Normal cow's milk, dried and powdered, gave the following:

Fat	4.5 % of total iodine
Protein	3.0 " " "
Serum (organically combined)	60.5 " " "
Serum (inorganic)	4.0 " " "

They concluded that only a very small part of the iodine of milk is in the inorganic form and that most of it is combined with the organic substances of the serum.

Where people do not have goiter or other manifestations of iodine deficiency they receive iodine in its organic relation as it exists in milk, vegetables and fish. There are one or more elements in this organic combination that not only determine the rate of assimilation but its availability as well.

DISCUSSION

J. C. GEIGER, M. D., F. A. P. H. A.

George William Hooper Foundation for Medical Research, University of California Medical School, San Francisco, Calif.

ONE of the striking things in medical history is the geographical distribution of goiter. The highest incidence is found in parts of the Alps, Pyrennees, and Himalayas; the Thames valley in England; certain inhabited districts of New Zealand; the region of the Great Lakes, and the northern Pacific Coast.

Chatin, a French chemist, in 1850 introduced the hypothesis that endemic goiter was due to iodine starvation or insufficient iodine in food and water. Some of the preventive measures used today were first mentioned by Chatin and forgotten, namely, potable water known to contain iodine, food grown in goiter-free regions, and iodized salt.

Marine's observations stimulated further interest in the theory of iodine starvation. Curiously, his reasonings were initiated when the use of iodine in water prevented thyroid enlargement in trout in hatcheries. Later Marine began his classical study with the children of Akron, O., and goiter surveys and chemical analyses of soils and water began in earnest. Apparently, wherever iodine content of water is less than 23 parts per billion goiter is common. Likewise, food grown in the so-called goitrous region may be low in iodine content.

McClendon states that oats grown in Minnesota contain 10 mg. of iodine per metric ton while near Wiscasset, Me., the content is 175 mg. This same author has recently published an exhaustive survey of the soils of South Carolina and, unfortunately, compared the results with those of California, to the detriment and chagrin of the latter.

Usually, the green vegetables, milk and fruits grown in goitrous regions are richest in iodine. There is little in wheat, and therefore flour, for it is mostly in the bran.

According to McClendon, the normal thyroid gland contains about 40 mg. of iodine. In experimental diets, the intake and outgo being carefully determined, it would require 40 years to accumulate 40 mg. Rochester, N. Y., adds iodine to its water supply, using about 1/10 lb. of sodium iodide per million gallons of water.

Historically, it is of interest to record data as to the Goiter Springs or Krapbrunner in Europe. These springs became quite celebrated because of the hope that the waters would produce goiter in those drinking it and debar the recruit from military service. The water was enormously filthy from the bacteriological standpoint.

One of the extraordinary facts of recent medicine and surgery is that goiter may be a factor in the occurrence of malignancy or cancer. For instance, in the Berne, Switzerland, area, an endemic center of goiter, the occurrence of malignant growths is about 1 to 100, while in the United States it is 1 to 1,000.

The clinical use of so-called glandular extracts in the treatment of cancer is based on the theory that one of the causes of cancer may be some unwholesome biological condition of the internal glands, particularly the thyroid and the suprarenal. There is no doubt that heredity plays its part in goiter as in cancer. Familial tendency to goiter has even occurred for three generations, and members of goitrous families have developed the disease or tendency while living in different regions. Shivers mentions the fact that there must be some reason why a goitrous mother will have goitrous children, particularly girls. King's opinion is that the simple adenomatous goiter is congenital and is subsequently stimulated by iodine deficiency, pregnancies, and mental and physical stresses. Exophthalmic goiter, however, depends on mental or emotional disturbances, trauma and shock. Finally, the colloidal goiter is due to iodine deficiency.

Jordi's feeding experiments on tadpoles in the laboratories of the Hooper Foundation of the University of California, using normal and abnormal thyroid, showed remarkable variations in growth, particularly with the normal. With this the animals showed marked decrease in size when compared to the usual controls. With abnormal thyroid, there occurred *specialized* effects on growth, indicating that dysfunction is by no means a minor clinical matter.

Whatever the cause or effect, the general public should note primarily the factor of iodine deficiency in food and water. General dosage of the people with iodized salt, chocolate iodine, or iodine in water supply should only be done under careful supervision of qualified physicians. Even then the question of goiter prevention in

the mass may be fraught with danger, and caution is urged accordingly. Moreover, it must not be overlooked that iodine in soil may or may not be in a soluble form and in different amounts in different types of soils. It appears that organic iodine in soil is a prerequisite for iodine containing vegetables. In addition, the significance of iodine in underground water supplies may overshadow the contents of surface soils. Likewise, appreciable quantities of iodine in food are not lost in cooking in the pot or processing in the can.

Apparently, as soon as the store of iodine in the thyroid gland falls below 0.1 per cent, the gland begins to enlarge. Finally, iodine can be safely given to those between the ages of 10 and 20 years living in goiter areas, but under medical supervision. Usually, small doses of iodine several times a year will guard against injury by the iodine.

Laboratory and Clinical Resources in Physical Examinations

THE appearance of articles in medical publications arguing the respective merits of clinical and laboratory methods is evidence that the medical profession has not fully comprehended the possibilities of preventive medicine. The complete physical examination of the apparently well does not necessarily require the use of all the laboratory aids at the disposal of the medical profession. At the same time, failure on the part of the examining physician to avail himself of the benefits of laboratory studies that he thinks unnecessary may result in a mistaken diagnosis. The patient who seeks a physician because of a discomfort that to his mind has not reached the dignity of an illness is entitled to receive the benefit of all the aids that clinical and physical laboratories have to offer. The question of cost should not enter into the calculation. If the patient is unable to pay, his recourse is the charitable institution. If the patient is able to pay, he should certainly not be denied the service.

* * * * *

Today physicians in increasing numbers realize that laboratory findings stimulate alertness of observation as well as compel more painstaking physical examinations. They are learning that when laboratory and clinical findings conflict, further clinical study of the patient will often explain the seeming discrepancy. Many things accepted as facts are based on wrong conclusions of preceding observers. Only careful and recorded studies of the apparently well and slightly ill will disclose such errors.—Keating, Emmet, M.D., *In at the Death*, *A. M. A. Bull.*, Nov., 1930.

Local Public Health Work in Mexico*

MIGUEL E. BUSTAMANTE, M. D., DR. P. H.

Assistant Director, Bureau of Communicable Diseases, Federal Department of Health, Mexico City, Mexico

IN Mexico, the Constitution makes the Federal Department of Health the supreme authority in matters of hygiene, and the *Sanitary Code* is the basis for federal action. The present program to help the cities toward the organization of their municipal hygiene is fostered and directed by the Federal Department of Health, with the coöperation of the most progressive and advanced states. The fundamental requirement for the formation and establishment of local sanitary institutions is the effective and substantial economical support of the local authorities. The existing health units carry on, thanks to a strong and generous federal support, which we hope will gradually give way to due appropriations from the local budgets.

When a state and a municipality, as happens in Veracruz, are ready to coöperate financially and administratively, the Federal Health Department is willing to give support, favoring and directing the establishment of permanent sanitary centers, which become a part of the community, doing a continuous beneficial hygienic work which can be seen and appreciated by the people.

While some states have boards of health with modern programs of preventive medicine and hygiene, others have no organization which could be rightly so considered, from the public health standpoint. As you are well aware, it has been difficult in all countries to awaken the municipalities and local authorities to their responsibilities in providing administrative and financial facilities for public health work. We read that to start the work in most counties of the United States it has been necessary to insure the coöperation of the U. S. Public Health Service and the International Health Board with the local authorities, which finally has resulted in the existing county health work with technical direction and economical coöperation on the basis of \$1 from the federal government, \$3 from the state government, and \$4 or more per capita from the municipality.

* Read at a Post-Convention meeting of the American Public Health Association in Mexico City (following the Fifty-ninth Annual Meeting in Fort Worth, Tex.), November 3, 1930.

A greater development of health units will come in Mexico when a legal provision is established to enable the Federal and State Health Departments to offer to those communities which will accept their responsibilities, effective technical advice along with proportional financial coöperation.

Coöperative health work began in the United States in 1920, and promptly spread all over the world, giving a new hope and a new element of victory to the hygienists of the world. In Mexico it was initiated in 1925, the first Mexican sanitary unit having been established in Minatitlan and Puerto Mexico in 1928, followed by one in Veracruz, May 17, 1929; one each in Tuxtepec, Oaxaca, and in Tierra Blanca, Veracruz, in 1930, forming the nucleus of city and rural modern coöperative health work.

The progress has not been so slow if we consider the difficulties of creating at the same time—parallel to the coöperative health organizations—a public spirit, comprehensive enough to ask for the services of sanitary organizations of an apparently complicated type. Here again the experiences of the United States and Mexico are similar, that is:

In the administration of public health the states are sovereign units, and the experiences gained in one state cannot be put to use in a less progressive state except by the process of demonstration, education and slow growth.

In our Republic, the type of rural communities where the public health activities are most needed is almost uniform in one respect—the lands of the municipality lie around a center where all the houses are grouped to form the village or town proper. We do not commonly see, as in the United States, the farm owners, their families and workers living on their respective lands, but rather in the villages or what we call "pueblos." The agriculturists start their daily work by a trip from the town to the surrounding fields, returning at sunset to the village where they live.

These towns all have market-places for exchange of daily commodities, using common water sources, either a river, various wells, or a spring. When the people move to sell their crops and products from one town to another, they all go on the same day and almost at the same time. This rural situation gives to the epidemics certain aspects, which good observers have followed on the map—as well as on the calendar. Dr. Pardo writing about a typhus epidemic, in 1915, in the City of Oaxaca and the neighboring towns, speaks about the spread of the disease from place to place following the market day in each: Thursday for Ejutla, Friday for Ocotlan, Saturday for Oaxaca, Sunday

for Tlacolula—the movements of the people in the Valley of Oaxaca, and the spread of the disease coinciding with their commercial relations.

The contaminated water of a source which is generally used for most of the people is equally dangerous for all inhabitants; instead of dealing with family typhoid the case is one of village typhoid. Our greatest general public health problem is the lack of adequate provision of pure water and its complement for the sanitation, sewage disposal. The heavy expense involved retards the solution. We do not ignore the facts and are anxious to correct them, but our limitations are those of any reconstruction period, overcrowded with many pressing problems. Among them are extension of popular education, good road communications, and modern disease prevention to reduce our high morbidity and mortality rates. It is not difficult to understand the amount of energy, the intensity of effort, and the greatness of the ideal which we need to carry us through a task of centuries in a score of years.

PUBLIC HEALTH IN VERACRUZ

As previously stated, the first coöperative sanitary unit was established in April, 1928, to work jointly in the municipalities of Minatitlan and Puerto Mexico. It has, as all the others have, the coöperation of the Federal Department of Health, the State Direction of Health, the two municipalities, and the International Health Board of the Rockefeller Foundation. This unit gives its services to a total population of 25,000 people and has the following fundamental principles:

1. The basis of all procedures is public health education.
2. All the sanitary personnel are chosen for their experience, training and standing.
3. All employees are full-time, devoting their energies to this one work. This applies to the Director, who is a full-time Health Officer.
4. The organization is permanent in the place where it is established.
5. The work is done with the strictest economy of expenditures.
6. Technical and financial support must be given in full coöperation by the civilian and sanitary authorities.

With this general basis, on May 16, 1929, the City of Veracruz witnessed the inauguration of a coöperative sanitary unit to serve a population of 70,000 people. The establishment of this unit constitutes a progressive step in the sanitary services of that city, because of its importance as Mexico's principal port, and because of the special services which the Federal Department of Health has maintained in Veracruz since 1920, with the object of preventing the return of yellow fever and bubonic plague to the country. The yellow fever campaign

VISITING NURSE, VERACRUZ

was extended some years ago to anti-larval work for malaria eradication, and its total accomplishments are a natural link and support to the new institution.

It was justifiable to pass from the campaigns against yellow fever, malaria, and bubonic plague, to a most comprehensive and extensive health program, with the desire to complete the hygienic work, using the results obtained by the expenditures of the preceding years to promote the control of other communicable diseases and to establish prenatal and postnatal clinics, to start school hygiene work, to provide laboratory facilities for diagnosis and prevention, adding sanitary engineering and inspection for the supervision and control of foods, particularly milk and water.

We must say here a few words about some high spots in the history of the sanitary work in Veracruz, and pay a tribute of admiration to the public health workers the effect of whose labor appears clearly in the mortality statistics of the past 40 years. Veracruz was a victim of yellow fever, malaria, tuberculosis, and gastrointestinal diseases up to 1903, when the first public health activities of significance were directed by the glorious Dr. Liceaga, then President of the Superior Board of Health.* His intelligence and influence had obtained, when the artificial construction of the port was about finished, the introduc-

* President of the A. P. H. A. in 1896.

tion of the water supply and the installation of the sewage disposal system, which were concluded in 1904.

With the sanitation, Liceaga started the modification of Veracruz, and September 1, 1903, began his famous campaign against yellow fever. His coworkers were Drs. del Río, Macías, García Iturralde and Manuel S. Iglesias, the latter three times vice-president of the American Public Health Association. He lives now in Veracruz and relates in very interesting articles how yellow fever was eradicated for the first time from that city in 1910. After bringing in the water supply, introducing the sewerage system and destroying the breeding places of the *Aedes Aegypti*, the health of Veracruz was marvelously improved. The crude annual death rate per 1,000 went down from 63.88, average for the 10 years preceding Liceaga's work, to 44.58 for the decade following. The rates for the principal causes of death changed as follows: gastrointestinal diseases, from 126.57 in 1898 to 46.20 in 1909; malaria, from 109.53 in 1903 to 38.96 in 1910; tuberculosis, from 124.86 in 1898 to 50.91 in 1911; and yellow fever from 191.61 in 1899 to disappearance in 1910.

Ten years later, 1920, Veracruz suffered the return of yellow fever which was extinguished in 1921 by the combined efforts of Drs. Malda, Lyster and Brioso Vasconcelos, Caldwell, Graham Casasús, Macías, Loyo and Ojeda Falcon. The same year brought a new scourge, bubonic plague, which however was quickly extinguished by the adoption of deratization measures. The statistics show a sad elevation to very high mortality rates from 1915 to 1920, and the return of the above mentioned epidemics imposed the necessity of renewed activity to solve the public health problems of Veracruz.

For years, attention was given only to the anti-larval and anti-plague services, from the results of which came the desire to reduce still more the too high morbidity and mortality rates. To do so, it was necessary to secure the coöperation of the federal, state, local, and International Health Boards, and in 1929, the coöperative Sanitary Unit of Veracruz was established.

The Sanitary Unit of Veracruz follows in a general way the principles and programs which the experienced public health workers, particularly those of the American Public Health Association, teach in the *Journal* and other publications, and also the advice given by European hygienists in the League of Nations papers relating to hygiene. Particular recognition is due also to the professors of the School of Hygiene and Public Health of the Johns Hopkins University and the International Health Board for their teachings.

The technical advisers of the Unit are: the Chief of the Federal

Health Department, the Director of the State Board of Health, the Sub-director of the Hookworm Campaign, representing the International Health Board, and the City Councilor of Sanitation, nominated by the City Government. This body of advisers constitutes the Superior Board of Technical Directors.

The institution is adapted to the particular conditions due to educational, psychological and economic factors prevailing in Veracruz. The organization has the following sections or bureaus:

SANITARY UNIT OF VERACRUZ

Direction with:

Education and training of personnel

Public health education:

Posters

Circulars

Lectures

Motion pictures

Vital statistics:

Collection from the Civil Register

Classification

Interpretation

Organization and administration

Communicable disease control:

Diagnosis, immunization, hospitalization:

Reporting

Maps and cards

Control practices

Antilarval service for:

Yellow fever prevention

Malaria control

Antirabic treatments:

Animal vaccination against rabies

Bubonic plague prevention

Smallpox vaccination

Typhoid and paratyphoid fever control

Tuberculosis control

Venereal disease control

General communicable disease control

Hookworm diagnosis, treatment and prophylaxis

A. Child Hygiene:

Prenatal service

Infant hygiene service

Visiting nurses and propaganda

B. School Hygiene:

Physical examinations

Dental hygiene

Visiting nurses

Laboratory:

Diagnosis and bacteriological examinations

Conservation and distribution of vaccines, serums, antitoxins, and chemical products used against malaria, syphilis, and dysentery

Preparation and distribution of material for collection of samples

Inspection of Foods and Beverages:

A. Veterinary Inspection:

Sanitary control of milk

Meat inspection and markets

Fish and shellfish sanitation

*B. Sanitary inspection of foodstuffs, refreshments, soft drinks, and food handlers**Sanitary Engineering:*

Street cleaning service

Inspection of sanitation in hotels, boarding houses, etc.

Technical advice in relation to the water supply, control of chlorination

Technical advice in relation to sewage disposal

Surface drainage, filling and ditch conservation for the antimalarial work

General problems of sanitary engineering

Building inspection

The program of work has been carried on since May 16, 1929. To begin with, there were taken on the then existing Federal Health Services, namely, the anti-larval, the anti-plague and the anti-rabic. The street cleaning which was previously done by the municipality was re-organized; all usable equipment repaired, and new and modern trucks were purchased to insure an efficient service. Immediately the Hookworm Clinic was initiated with treatments and lectures, the laboratory opened, and meat inspection established. In addition, reporting of communicable diseases, home visiting, and measures of control began to be taken. By the middle of August, 1929, the Venereal Disease Clinic was ready, and by the end of the same month the prenatal and postnatal centers were opened. In November, the work of school hygiene was initiated, and finally on January 26, 1930, we had the satisfaction of completing the organization of a Maternity Home and

HOOKWORM CLINIC, VERACRUZ

Nursery School under the administration of the Veracruz Sub-committee of the National Association for Infant Protection, which though separated from the Health Unit, economically and administratively, depends upon the medical services and advice of the director and technical personnel of the Sanitary Unit.

The kindness of the women in charge gives to us the full coöperation of their association, and with their help, our program for child hygiene goes as follows:

Prenatal care—Given in the clinic of the Sanitary Unit. Examination, instruction and care of pregnant women.

Natal care—In the Maternity Home of the local Committee for Infant Protection.

Postnatal care—From birth to 2 years of age, in the clinic of the Sanitary Unit.

Preschool hygiene—From 2 years to school age in the nursery school of the Committee for Infant Protection.

Hygiene of the School Child—Physical examinations by the Child Hygiene Section of the Sanitary Unit.

In Veracruz the principal obstacle is the lack of public health education. Although the people are ready to accept clear explanations, the general bystander thinks that the principal occupation of the department should be the correction of nuisances, particularly if they produce offensive odors. The Health Officer is very often transformed into a judge of complaints which belong to the police or are matters of the city ordinances and not of the sanitary laws.

At present our outstanding problems are the reduction of morbidity and mortality for gastrointestinal diseases, tuberculosis, and typhoid fever. To compare the changes in the numbers of deaths and death rates of the mentioned diseases Table I is presented. Yellow fever, bubonic plague, and smallpox have been eradicated. Tuberculosis, which had the rate of 1,250.5 per 100,000 in 1892, still had the high rate of 423.8 in 1928; however, the lowest in 39 years.

There is at present a general decline. Deaths from gastrointestinal diseases were at the lowest rates known in Veracruz from 1907 to 1911. They went up in 1915, and these diseases remain now the principal causes of death.

Malaria was so high early in the century that it occupied the first place among the causes of mortality in 1903, but the work against yellow fever and general sanitation brought the rates down, only to rise again in 1915, going above tuberculosis in 1918 and 1919, and from then on the fall has been constant, due to the anti-larval work, with the result that last year malaria ranked 8th as a cause of death. Oiling, stocking with minnows, drainage, filling of swamps and Paris

OLD TYPE OF MILK MEN SELLING MILK FROM HOUSE TO HOUSE

green are used against malaria. House-to-house inspections and destruction of breeding places are a daily feature of the anti-mosquito work.

In 1929, the crude death rate of 27.55 per 1,000 was the lowest in the 40 years of our statistics. For the 9 months of 1930 the rates are: birth rate, 44.39 per 1,000; crude death rate, 26.14 per 1,000; infant mortality, 100.15 per 1,000 living births. To be sure, we are not satisfied, but merely encouraged by present conditions. However, our desire and effort is to reduce further the rates to approximate those of the leading countries in public health work, particularly the United States, where our knowledge of sanitary science has its source.

Following the example of other cities in the reduction of disease we began to attack the water-borne diseases, among other measures petitioning the Committee on Material Improvements and the municipality to chlorinate the water supply, for which they installed a chlorinator February 22, 1930. Unfortunately the water supply and sewerage systems, adequate in 1903, are entirely insufficient and in bad condition for 1930, due to the increase in population, extension of the city's boundaries, and lack of thorough repairs.

A milk ordinance for the State of Veracruz issued to take effect February 17, 1930, has been applied gradually in the City of Veracruz and the following changes have taken place in one year. In May, 1929, all milk was sold from house to house by men on mules or horses.

TABLE I
CRUDE DEATH RATES, CITY OF VERACRUZ, MEXICO—1891-1929
ALL CAUSES AND PRINCIPAL CAUSES OF DEATH

Years	Popu- lation	Number of deaths excl. of still- births	Death rate per 1,000	Deaths due to gastro- intestinal diseases	Death rate per 10,000	Deaths due to tubercu- losis	Death rate per 10,000	Deaths due to yellow fever	Death rate per 10,000	Deaths due to typhoid fever	Death rate per 10,000	Deaths due to small- pox	Death rate per 10,000	Deaths due to bubonic plague	Death rate per 10,000

1929	69,367	1,938	27.93	485	70.91	307	0.00	0	6.34	38	5.49	0	0.00	0	0

Less than 1 per cent of the supply was bottled, none was refrigerated, and there was widespread adulteration and use of chemical preservatives. By February, 1930, all milk was bottled, handled in especially equipped distributing centers, called "Lecherías," which are required to be painted white and screened, and distribution is done by means of trucks or milk wagons. By August, 1930, more than 75 per cent of the supply was refrigerated at 10° C., and we expect shortly to have 100 per cent milk refrigeration. The daily inspection and laboratory examinations show that adulteration and use of chemical preservatives have been reduced to 0.11 per cent.

The general public is open minded and receives willingly the new services when they show their advantages. Mothers visit freely the prenatal and postnatal clinics, and the attendance of pregnant women has increased steadily from August, 1929, to August, 1930. The monthly average of new examinations is 52, with 237 reexaminations and 17 deliveries of mothers visiting regularly at the clinic. The examination of infants brought for advice has increased from 142 per month for 1929, to 282 per month for 1930, an increase of almost 50 per cent. The follow-up work done by the visiting nurses gives good contact with the people, and generally they are well received by the mothers and families.

The hookworm clinic shows proudly 17,798 treatments in 17 months, an average of 1,450 per month, without any serious accidents. Two hundred and sixty-four lectures have been given and practical demonstrations of hookworm eggs and larvae are used as educational methods.

For 16 months not a single case of smallpox has been recorded in the city. The venereal disease clinic, the first to be established for public health work in Veracruz, has had a monthly attendance of 150 patients. Moving picture propaganda has been shown at clubs, unions and lodges.

The laboratory service makes constant analyses of water, milk and other foodstuffs; examinations are made for diagnosis of malaria, typhoid fever, syphilis, tuberculosis and other diseases. The fecal examinations for intestinal parasites have shown 7,074 positive specimens for hookworm eggs; 5,929 for ascaris; 12,566 for trichocephalus.

The Sanitary Engineering Bureau has controlled the chlorination of water and ice, the drainage and filling of swamps for anti-malarial work, street cleaning service, and building and housing inspections. Among the principal works accomplished are the construction of the Avenida Cuauhtemoc ditch, and the straightening of the Avenida Revillagigedo channel, which have saved the city from the inundation of the sand dunes' water shed.

The personnel is 100 per cent full time, honest and enthusiastic, and it is due to their earnest work that something has been accomplished. The Federal Health Department has given full support without any restrictions, and their generous attitude is particularly responsible for the existence of the Unit. Their part of the budget is 84.24 per cent. The State Direction of Health has given aid to the budget of 1.71 per cent, and has published different ordinances. The city, due to financial conditions, has not been able to increase its share, 12.33 per cent, but has accepted suggestions from the Unit for water purification. There is a strong general and popular desire to obtain for the city a good water supply and sewage disposal, which will prove an immense good when completed, with the support of the Board on Material Improvements. The Rockefeller Foundation contributes 1.71 per cent of the budget, and has an adviser on the Board of Directors.

Besides the already existing Units in Veracruz, Minatitlan, Puerto México, Tuxtepec and Tierra Blanca, other cities are organizing local health services. All states have delegations from the Federal Department of Health, and many of them local councils of hygiene. In different towns we notice a growing interest in the organization and development of the Units, and because of the ever progressive and modern ideas of the authorities of the Federal Department of Health we are sure that the municipalities with enough civic spirit and desire to pay for their own health will make a good investment, with a proportional support from the Federal Government.

Then with all the nation working for its health, united in a good program of disease prevention and health promotion, the present generation will see passing forever from our statistics thousands of preventable deaths, the coming of healthier citizens, and medical science not only the consolation of the sufferer and cure of the sick, but the teacher and provider of a healthier and happier life.

Pasteur, Koch, Ross, Gorgas, Finlay, Liceaga, Ferrán, Cruz, Carrión, heroes of humanity, have passed from hand to hand the torch of light for us to follow.

The Public Health Nurse in a Rural Health Department

An Introductory Report on the Study in Progress in Cattaraugus County*

MARIAN G. RANDALL, R. N.

Division of Research, Milbank Memorial Fund, New York, N. Y.

THE generalized public health nurse is recognized as so important an agent of the present and future health department that the development of her activities requires careful consideration and appraisal by those who are interested in the trend of public health administration and in the evaluation of its results. In those localities where a generalized nursing system has been put into operation, more and more manifold duties are being assigned to the nurse; greater responsibilities are being placed upon her shoulders; and a keener initiative is being demanded of her. In fact, her very designation as "nurse" is becoming a misnomer, for she is expected to be also the teacher and sanitarian who is required to carry into the home, school, clinic, and welfare station, the interpretation and explanation of modern hygiene, and put into effect the approved and newer measures for prevention of disease and promotion of health.

These newer functions are well illustrated in the experience of the Rutherford County Child Health Demonstration which was that the generalized nurses "proceeded to occupy—as completely as they could in view of the scattered rural population—all the accepted fields of public health nursing service," and "the shuttle services between the health department, the private practitioners, and the individual, tended to unify and simplify, in the popular mind, the meaning of the whole enterprise."¹ Or again, in reviewing the experience of the general health demonstration in Cattaraugus County, it was stated:

The public health administrator realizes that scarcely a wheel can turn in his health machinery without the nurse. To say that she is indispensable to the program does not cover the fact. To a great extent, her work *is* the program. It is one thing to have a certain number of nurses. It is quite another to have the work

* This is the first of a series of papers presenting the results of studies of public health nursing in different types of official health administrations.

of these nurses thoroughly interrelated with an active clinic service, with systematic communicable disease control, with comprehensive local laboratory work, all properly set in a routine that binds the whole into one fabric.²

It is inevitable that, in the process of this development, some confusion exists as to what the proper functions of the official public health nurse are and as to what directions they should take. This is evident in the current discussions of the precise rôle the generalized nurse should play in the many activities in which she already is engaged; of the amount of time that she should give to school hygiene, or to infant welfare, or to tuberculosis or other public health activities in order to bring about what we like to call a "well balanced program"; of whether or not less professional training as a nurse and a greater emphasis on public health training would fit her better for the job which she has to do; and of the persistent question of generalized versus specialized public health nursing. It would seem that the time has come, at this stage of the development of the official public health nurse, for more or less detached studies of the actual work performed by her in different types of rural and urban health administrations.

These studies should help in answering questions as:

To what extent does the public health nurse serve the entire population of different types of communities and in different types and kinds of health administrations?

Using records of births, school defects, illness among school children and in the general population, the findings of examinations and inspections of preschool children, communicable disease reports, clinic records of tuberculosis, venereal disease and the like, as indications of the demand or the needs for nursing services—to what extent does the official public health nurse supply this demand or meet these needs under varying conditions?

How effective is the work of the public health nurse in accomplishing its objectives in each specific activity in which she engages?

To what extent does she come into contact with conditions not reached through channels already provided by the official and voluntary agencies?

What duties now performed by the public health nurse could be performed by some other type or types of workers without, perhaps, her professional training, but with more specialized training in certain directions?

What is the "case load" of a public health nurse working in an official health administration?

What basic considerations should be taken into account in formulating the nurse's program of work if an analysis of her job is made from the point of view of the administration as a whole?

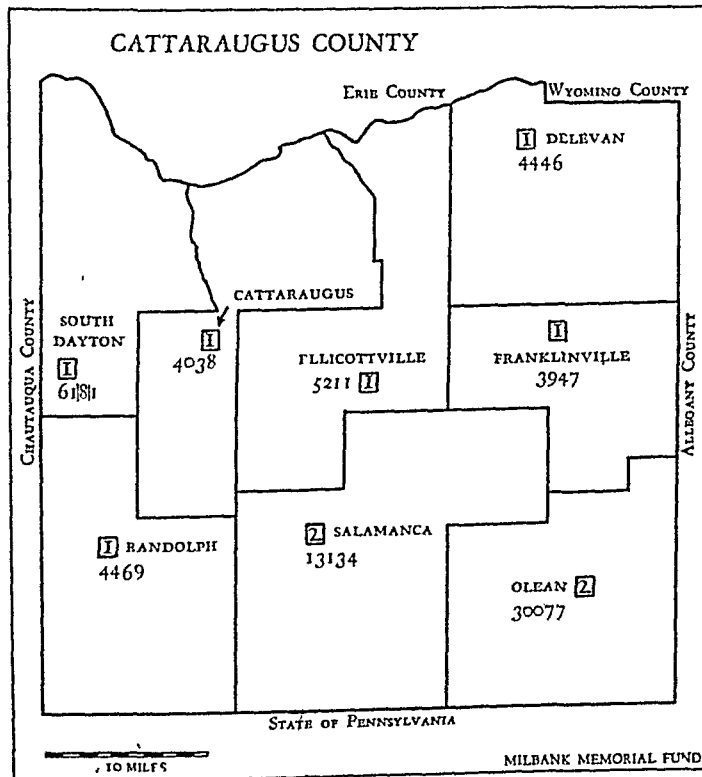

To what extent do physical factors interfere with the performance of her duties, such as distance, the weather, and the condition of roads?

It is easy to theorize in attempting to answer such questions as these and to set up programs of work and schedules of activities that

look well on paper, and even to formulate standards, such as those tentatively set forth in our "appraisal" forms. Obviously, the more factual data available, the more accurate will be our analyses, and the more sound our conclusions and our standards. By factual data is meant not merely the statistical record of the volume of work of the nurse, but the more intimate picture of conditions under which she "carries on"; the problems which she encounters; the services she actually renders; and the things she is able to accomplish.

As a beginning in a series of studies of the work of the official public health nurse, the Research Division of the Milbank Memorial Fund naturally turned to the experience of Cattaraugus County, where the Fund has been assisting in the establishment of a well rounded county health department. This paper is an introduction to the more complete reports in preparation, and deals specifically with the *home visits* of public health nurses. The experience of the nurses in all phases of the work for a year will form the basis for the more complete reports. The following discussion utilizes a sample of the records that represents the actual experience in home visiting of approximately the equivalent of 3 nurses for 6 months. It is offered as a progress report on an experiment in the collection and use of data for the purpose of throwing further light upon factors requiring administrative consideration.

The Cattaraugus County Health Department, serving a primarily

Map showing the division of the county according to nursing districts, with the population of each, exclusive of Indians. The squares indicate the location of the district health stations, and the numeral within the square, the number of county staff nurses working in that district.

The central administration office is in the Olean district. The city of Olean, with a population of 21,350, employs school and city nurses. There is also in this district a community nurse supported by the residents of Portville to serve its population of 1,435.

One of the county nurses in the Salamanca district serves a population of 9,900 in a concentrated urban area. The city of Salamanca employs a school nurse.

rural area of 1,343 square miles, has sponsored a generalized nursing service for several years. The number of staff nurses has varied from 14 to 10, the present personnel consisting of a director of the Bureau of Nursing, 2 supervisors, and 10 staff nurses. The population of the section allotted to each nurse has varied from approximately 3,500 to 4,500, the latter figure representing the present average potential group for which a nurse carries on all the public health nursing activities of the health department.

NATURE OF RECORDS USED

In order to obtain the desired information it was found necessary to supplement the records already in use. From the existing system of nursing records, it was not possible to obtain comparable data for all home visits.* For example, single communicable disease visits were not recorded on any record form giving information relative to the individual visited. Again, it was not possible to relate the nurses' home visits made in the interest of getting school children's defects corrected to the number of children visited, because a definite record of visits was not kept on every individual school child's record card. For purposes of complete analysis of the nursing activities this information is just as important as that on the record of the individuals visited in the interest of tuberculosis control.

Accordingly, and with the assistance of the Milbank Fund's staff, a new and simplified record system was instituted by the health department in February, 1930, which made provision for recording comparable data for every home visit. These data include information regarding the source of first information about the case, the nature of the problem, date of visit, services rendered at the time of each visit, results, and the reason for termination of the case. In other words, they were intended to record answers to these questions: "Why did the nurse visit? What did she do, and what happened?" As a further aid to making data comparable, emphasis was given to the importance of uniformity in recording the content of the nurses' visits.

A family folder was already in use which contained nurses' records for all members of the family, but with the new record system all information concerning the family is filed in this folder, namely, social history, clinic records, nurses' records, and special reports. These are filed in the 8 district health stations where the clinics are held and the

* Two reasons for this were (1) a certain lack of uniformity in recording the content of the nurses' visits, and (2) the prevailing practice of the nurse not keeping a record of the single health education visit made as a health department representative other than including it in her daily summary report of the total number of visits made.

nurse has her office. With the exception of a family index card, no records are kept in the central office, the distances making decentralization of records far more satisfactory.† When a family folder is not "started," the comparable data regarding the single health education visits are recorded on call slips. The complete information from these call slips makes available certain data heretofore incomplete.

A comparison of the number of visits represented in the sample of records used for this report with the reports of the total visits made by all the nurses on the staff in the same 6 months is shown in Table I. Since the percentages of visits made to individuals in each age group are so similar, it seems reasonable to conclude that the sample adequately represents the distribution of visits according to problems and age groups.

TABLE I

COMPARISON OF SAMPLE OF RECORDS WITH REPORTS OF TOTAL VISITING BY ALL THE COUNTY HEALTH DEPARTMENT NURSES, ACCORDING TO NUMBER AND PER CENT OF VISITS TO CASES IN EACH AGE GROUP
(February 1 to August 1, 1930)

Age Group	Number of Visits		Per Cent of Visits	
	Sample of Records	Reports of Total Visiting	Sample of Records	Reports of Total Visiting
Infant	240	1,422	16.4	15.4
Preschool	327	2,425	22.4	26.3
School	571	3,033	39.1	32.8
Adults	232	1,655	15.9	17.9
Maternity	89	702	6.1	7.6
TOTAL	1,459	9,237	99.9	100.0

THE EXTENT AND NATURE OF HOME VISITING

The indication afforded by our sample as to the extent of certain phases of the work done by generalized public health nurses in home visits in a rural area is summarized in the following tables and comments.

Assuming that the sample of data showing 1,459 visits to 733 individuals represents the ratio of individuals visited to visits made, it is estimated that 1 individual is visited for every 2 visits. Applying this ratio to the 9,237 visits recorded in the reports of the total work, it is estimated that 4,618 individuals or approximately 9 per cent of the

† A family folder index card containing a minimum amount of information is filed in the central office. This is sufficient to permit clearance of cases with the social Confidential Exchange and facilitate transfer of a record if a family moves from one district to another in the county.

TABLE II

DISTRIBUTION OF FAMILIES ACCORDING TO STANDARD OF LIVING

Standard of Living	Number	Per Cent
Well-to-do	8	2
Comfortable	50	12
Moderate	199	49
Poor	113	28
Very Poor	35	9
TOTAL *	405	100

* Excluding 21 families for which standard of living was not recorded.

total population* were visited by the county department of health nurses in 6 months. This probably means that the nurses visit about 14 per cent of the population in a year although later studies of the total year's work may modify this figure. This refers to the number of persons who received *any* home visit or visits from the public health nurse, regardless of the problem or several different problems occurring during a given year. The usual reports of official organizations do not give information regarding the per cent of the population receiving public health nursing service.

The economic status of the people visited is indicated approximately in Table II, which presents the nurses' classification of 405 families.

TABLE III

DISTRIBUTION OF 426 FAMILIES ACCORDING TO FREQUENCY OF VISITS BY 3 PUBLIC HEALTH NURSES IN 6 MONTHS

Number of Visits*	Families	
	Number	Per Cent
1	265	62.2
2	61	14.3
3	34	8.0
4	21	4.9
5	16	3.8
6	6	1.4
7	7	1.6
8 or more	16	3.8
TOTAL	426	100.0

* Total of 938 visits to 426 families.

* The preliminary 1930 census figures for Cattaraugus County, exclusive of Olean City, show a population of 51,246.

Table III, a tabulation of the frequency of nurses' visits to 426 families, shows that 62 per cent of the families received only 1 visit. Similar information is given in Table IV, showing the frequency of the visits to the individuals in these families. With the exception of the infant group, 50 per cent and over of all the individuals visited received but 1 visit in 6 months. In both instances, there are included families and individuals for whom service was begun toward the end of the 6 months' period, as well as those who had been receiving nursing visits prior to the stated period. Since the number of visits for a particular problem is not complete, this cannot be thought of as information pertaining to the nursing service as it relates to the particular family or case, but rather as a cross-section of the nursing service given by 3 nurses in a 6 months' period.

How the nurses happen to know about the people to be visited is shown in Table V, which is a tabulation of the source of first information about the cases visited. This information from our sample of records shows that 54 per cent were reports or requests from the official organization. These include reported cases of communicable disease, birth registration slips, and school reports of children with defects needing correction. It is to be expected that a large percentage of such information would come through official channels, but the records serve further to emphasize the selective influence of the organization machinery in determining what work is to be done. The small percentage of the nursing service originally sought or requested by individuals outside of official channels is a point for consideration in for-

TABLE IV

FREQUENCY OF THE HOME VISITS MADE TO INDIVIDUALS IN EACH AGE GROUP,
BY 3 PUBLIC HEALTH NURSES IN 6 MONTHS

	No. of Individuals Visited	Total No. of Visits	Frequency of Visits				Per Cent Distribution of Visits				
			1	2-4	5-7	8 or more*	Total	1	2-4	5-7	8 or more
Infants	75	240	29	29	10	7	100.0	38.7	38.7	13.3	9.3
Preschool	168	327	100	60	6	2	100.0	59.5	35.7	3.6	1.2
School	369	571	274	82	12	1	100.1	74.3	22.2	3.3	0.3
Adults	93	232	54	27	6	6	100.0	58.1	29.0	6.5	6.5
Maternity	28	89	14	7	3	4	100.0	50.0	25.0	10.7	14.3
TOTAL	733	1,459	471	205	37	20	99.9	64.2	28.0	5.0	2.7

* Individuals receiving more than 8 visits are distributed as follows: infant, one each 11, 16 and 19 visits; preschool, one 10 visits; school, one 9 visits; adults, one each 9, 10, 11, 16 and 19 visits; maternity, two 9, one each 14 and 17 visits.

mulating the health education program. An important phase of the family health work is indicated by the fact that 24 per cent of the cases visited first became known to the nurses through home visits to some other member of the family.

GENERAL TYPES OF HOME VISITS

In order to describe more clearly the work of the generalized public health nurse in an official health administration, it is desirable to

classify the home visits into some such categories as the following:

1. Single health education visits
2. Case visits
3. Bedside care visits

These categories may be defined thus:

Single Health Education Visit—This type of visit, peculiar to the nurse in the official organization, may be, for want of a better term, classified as the departmental call or the single health education visit made as a health department representative. It is illustrated by the single home visit made to a reported case of communicable disease, the 1 visit to an infant following the birth certificate report, or a visit to a school child to urge the correction of a physical defect.*

Case Visit—Case visits or the more or less intensive and repeated home visiting to disseminate health information and give health supervision for 1 or more members of the family, such as: the maternity case, visited several times in both the prenatal and postpartum periods; or the preschool child who presents nutritional and behavior problems; or the tuberculosis case and family contacts, all of whom require careful routine observation and supervision.

Bedside Care Visit—The visit in which bedside care is given at the time of illness, either in a case of emergency or to demonstrate to the family how to care for the patient.

The single home visit or departmental call is made necessary by the requirements of the health department program. If each nurse serves a population of 4,500, it is impossible for her to make repeated visits and give intensive health supervision to all cases with which she comes in contact. Since all types of visits were included in the sample of records collected, it was possible to make the analysis shown in Table VI, according to the amount of visiting to an individual. In this sample of records, 56 per cent of the individuals visited received single health education calls. This fact is sufficient evidence of the necessity for taking into full account this type of visit when studying the activities of the nurse in the official health department.

Since the sample of records used represents only a cross-section of home visiting for 6 months, an analysis as related to particular cases must of necessity be reserved until more complete data are collected.

* More than 1 visit might be desirable or ideal, according to accepted or proposed standards, for any one or many of the individuals in this group. It is impossible, however, for the nurse in the official health department to give continued supervision in the form of repeated home visits to all the individuals or patients with whom she comes in contact; therefore a selection is necessary. Several visits are, of course, made to some cases of communicable disease, to certain school children whose defects need correction, and to some infants whose birth certificate first informed the nurse of their existence; but the fact remains that there is a large group who receive only a single visit.

TABLE VI

INDIVIDUALS IN SPECIFIC AGE GROUPS, CLASSIFIED AS THOSE RECEIVING EITHER A SINGLE HEALTH EDUCATION CALL, OR REPEATED FOLLOW-UP VISITS FROM THE PUBLIC HEALTH NURSE

Age Group	Number of Individuals			Per Cent of Individuals		
	Receiving Several Follow-up Visits*	Receiving Single Health Education Visit†	Total	Receiving Several Follow-up Visits*	Receiving Single Health Education Visit†	Total
Infant	60	15	75	80	20	100
Preschool	80	88	168	48	52	100
School	124	245	369	34	66	100
Adult	37	56	93	40	60	100

TOTALS	322	411	733	44	56	100

* As revealed by "case histories."

† As revealed by "call slips."

Our sample, however, throws some light on the sort of information that an analysis of records of this kind may yield.

There were 129 school children (in households where only school children were visited) who received a single home visit for the purpose of urging the correction of a physical defect found at the time of the school medical examination. The results of these visits are tabulated in Table VII. Subtracting from this total group the 26 instances where, as far as the public health nurse was concerned, the problem had been met, namely, "corrections had been made" (11), "children were receiving treatment" (6), "private physician or dentist had

TABLE VII

RESULT OF PUBLIC HEALTH NURSES' SINGLE HOME VISITS TO SCHOOL CHILDREN TO URGE CORRECTION OF PHYSICAL DEFECTS

Result	No. of Children	Per Cent
Corrections had been made	11	9
Children were receiving medical or dental treatment	6	5
Parents reported that physician or dentist had been consulted and said corrections were not necessary	9	7

Parents refused to consider having corrections made	13	10
TOTAL*	128	100

* Excluding 1 child for whom result of visit was not recorded.

reported correction not necessary" (9), and the 1 case of unknown classification, leaves 102 instances of this problem. Of these, 34 or 33 per cent stated they could not afford to have corrections made. Since the nurse cannot usually offer free dispensary or clinic service, she is handicapped at this point, and a very definite problem is presented. This leaves 68 instances where the result of a single visit might be classified as successful or not successful, the former recorded as "Parents promised to have corrections made" in 55 or 81 per cent of the 68 cases, and the latter as "Parents refused to consider" in 13 or 19 per cent. If so considerable a proportion of parents were found to be non-coöperative, a definite problem in health education would present itself.

A similar kind of information is given in Table VIII in which are tabulated the results of public health nurses' home visits to preschool children for the purpose of urging protection against diphtheria by toxin-antitoxin. Of the 74 known as to classification there were 8 who had had the treatments, leaving 66 to be analyzed in terms of success or failure of the nurses' visits. If we consider the parents' promise to take the child either to clinic (29) or to private physician (7) as satisfactory, there were 35 or 53 per cent successful "results." The parents' refusal in 16 or 22 per cent might be classified as unsuccessful and the 15 or 25 per cent in which the parent promised to consider the matter as "cases to be followed up." In this instance the free toxin-antitoxin clinic eliminates the possibility of children not having protection against diphtheria because their parents cannot afford to pay for the treatments.

A comparison of the "results" in these two phases of the work shows that even with the facility for free treatment in the case of toxin-

TABLE VIII

THE RESULT OF PUBLIC HEALTH NURSES' HOME VISITS TO
PRESCHOOL CHILDREN TO URGE TOXIN-ANTITOXIN

Result	No. of Children	Per Cent
Child had had the treatments	8	11
Parents promised child would attend clinic	28	38
Parent promised to take child to private physician for treatment	7	9
Parent promised to consider the matter	15	20
Parent refused to allow child to have treatment	16	22
TOTAL*	74	100

* Excluding 7 children for whom result of visit was not recorded.

antitoxin there is a higher percentage of unsuccessful visits for "TAT" than for "correction of defects." This is to be expected, perhaps, since the toxin-antitoxin represents the newer phase of prevention as against the older idea of correction; but the fact suggests a specific direction in which further emphasis may be given in health educational work.

That all infants visited by the public health nurse received more or less of a certain routine service in the form of, (1) advice to the mother regarding the general care and feeding, (2) an invitation to attend the Child Health Conference, and (3) an explanation of the need for and value of preventive measures such as toxin-antitoxin, does not seem too great an assumption, but a more complete indication of the results of such service is given in a sample record of what the nurses actually accomplished. The records of 75 infants visited during the 6 months showed that only 25 per cent had attended the Child Health Conference, and 25 per cent had received toxin-antitoxin. Some of the infants may have received only a single visit from the public health nurse, at which time but one problem was discussed. Perhaps many of the infants who had not had toxin-antitoxin were only 1 or 2 months old, and some of those who had not attended the Child Health Conference may have been under supervision of private physicians. The point to be considered is the reason why a larger percentage of success was not possible, and this will be attempted later in a more complete analysis related to particular cases.

Another type of visit which is influenced by the official organization is that in which bedside care is given in illness. This type of service is not included in the program of many official organizations, but in the rural sections of Cattaraugus County, where there are no

TABLE IX
HOME VISITS BY PUBLIC HEALTH NURSES TO GIVE BEDSIDE CARE

other agencies to which cases can be referred, the County Health Department offers bedside care either in a case of emergency or as a demonstration to teach the family how to care for the person "sick in bed." In the sample of records analyzed, the number of individuals who received bedside care (49) represents 7 per cent of the total visited, and the number of visits (146) for this purpose, 10 per cent of the total visiting. Table IX shows the number and distribution of visits.

TABLE X
DESCRIPTION OF BEDSIDE CARE GIVEN TO 20 ADULTS

No. of Adults	Condition or Need for Care	Actual Service Given at Time of Home Visits	Total Number of Visits
		<i>One demonstration visit to teach a member of the family to give care:</i>	
5	Old Age—Bedridden	Gave bath, made bed, made patient comfortable. Demonstrated care necessary to prevent bed sores.	5
2	In Automobile Accident	Gave bath, applied wet dressing to cuts and bruises as per physician's orders.	2
2	Erysipelas	Gave bath, applied dressing to affected areas, demonstrated isolation technic to practical nurse who was caring for the patients.	2
1	Injured Finger	Applied first aid dressing to finger.	1
1	Measles	Gave bath, changed bed, made patient comfortable and demonstrated isolation technic. <i>More than 1 visit, emergency situations. No adult in home to care for patient:</i>	1
1	Tonsillitis	Swabbed throat.	2
1	Acute Intestinal Disturbance	Gave bath, made patient comfortable.	2
1	Nephritis	Gave bath, prepared special diet ordered by physician.	3
1	Old Age—Heart Condition	Gave bath, changed bed, made patient comfortable, took pulse and temperature, reported condition to physician.	4
1	Old Age—Paralysis	Gave bath, made patient comfortable (patient moved to hospital).	5
1	Pneumonia	Gave bath, applied pneumonia jacket, took temperature and reported to physician.	5
1	Cystitis	Gave bladder irrigation.	16
1	Tuberculosis	Gave bath, changed bed, sterilized dishes (advanced case).	19
1	High Blood Pressure	Gave general hot pack (lasting one hour).	21
20		TOTAL	88

Adults constituted over 40 per cent of the individuals who received this type of service, and to illustrate the possibilities of drawing a more intimate picture of the work, a description of the actual services rendered to these 20 adults is shown in Table X.

SUMMARY

The increasingly important part which the public health nurse is taking in all of the activities of the official health department organization is sufficient evidence of the need for careful analyses of the nature of her work, appraisals of its results, and a critical consideration of the directions in which it can develop most fruitfully.

The necessary records for such a consideration are not ordinarily available in the purely administrative reports. Without adding to the burden of record keeping, the nurses' reports can be revised in such a way as to make the desired information available.

In the course of certain studies of the work of the official public health nurse, a preliminary consideration of a sample of records from Cattaraugus County, representing the actual experience in home visiting of approximately the equivalent of 3 nurses for 6 months, suggests the usefulness of records of this kind. It was indicated that:

The nurses make home visits to 9 per cent of the total population in 6 months and probably about 14 per cent in a year.

Only 1 visit was made to 62 per cent of the families.

For 54 per cent of the people visited, reports or requests for visiting came through official channels, illustrating the selective influence of the organization machinery. In 24 per cent of the cases the individual was first known to the nurses by reason of visits to other members of the family.

The so-called single health education visit is made necessary by the requirements of the official health department program. Of the individuals visited 56 per cent received single health education calls.

An adequate, though simple, record of the "results" of home visits reveals the nature of problems to be attacked by the health department. For example, it was found that in 23 per cent of cases visited for correction of defects the family stated that they could not afford to have the corrections made, thus suggesting a problem in economics. About 20 per cent of the cases revealed uncoöperative families, suggesting the need for further health education.

The precise character and extent of the bedside care given by rural public health nurses can be depicted by adequate records of what is done in such instances.

Fiji Carries on for the Children

FIJI Island mothers staged a child-welfare meeting at the Agricultural Show held last year in Suva, Fiji, according to a report by Dr. Regina Flood-Keyes Roberts, the wife of the American consul at Suva. Dr. Roberts carries on volunteer child-welfare work in the vicinity of this capital of a British possession. She reports that two Fijian students at the Central Medical School are now being trained by her for the work, accompanying her on her rounds of the villages. Senior students are also invited to go with her on these visits. A student trained last year was, on graduation, assigned a district, and he is reported to have been doing good work.—U. S. Children's Bureau, Washington, D. C.

Diphtheria Prevention in Detroit*

HENRY F. VAUGHAN, DR. P. H., F. A. P. H. A.,
AND CARL E. BUCK, DR. P. H., F. A. P. H. A.

*Commissioner of Health, and Deputy Commissioner of Health and Executive
Officer, Detroit, Mich.*

THE question of diphtheria prevention in Detroit is a very serious one, for we have today the highest diphtheria death rate of any large American city. Detroit started its diphtheria prevention work in the year 1921 by offering diphtheria protective treatments, in the schools, to those children whose parents would consent to have them protected.

There was a gradual increase in the number of children protected, mostly school children, until the year 1926 when there was a very pronounced rise. This increase was due primarily to two reasons—(1) More money was spent upon diphtheria prevention that year, with the establishment of a large number of clinics. (2) This was a year of high incidence of diphtheria and a very serious form of the disease made its first appearance.

There was a pronounced drop in the number of immunizations against diphtheria in 1927 and a further drop in 1928. This falling off in number of children protected may be attributed to two factors—(1) The high incidence and severe diphtheria of 1926 having passed, the scare was over and people began to lose the fear of the disease which had been aroused during the preceding year. (2) The most easily reached portion of the population had already had their children protected. We were beginning to run into that group of parents which is more difficult to rouse to action.

In the year 1928 it was felt that sufficient educational work had been done on diphtheria prevention to warrant placing the entire responsibility for giving diphtheria preventive treatments and the Schick test in the hands of the practising physician where we believe it rightfully belongs. The details of the plan and how it is working out will be described.

In view of the fact that the plan of turning over to the physician the responsibility for diphtheria prevention is only part of a definite

policy to which we hold, it may be wise to digress for a moment and describe this policy.

If we agree that the goal toward which we are aiming is universal participation in procedures of preventive medicine and health promotion, then some group or groups of individuals must be prepared and ready to meet the demand for service which this goal would entail. To put it more simply, if we expect all persons, young and old, to do the things which we think they should to prevent disease and maintain good health, the services indicated will have to be supplied by some group or groups of individuals. It is our contention that it is unreasonable to expect any large reasonably well-to-do community itself to supply sufficient funds and personnel

to provide all the services necessary to insure universal participation in the field of preventive medicine and health promotion. From whom then can these services be obtained, except from the private physician, dentist, nutritionist, psychiatrist, etc.? If these hypotheses are well founded the official health organization has two important functions to perform.

1. To create a demand on the part of the people of the community for well proven scientific procedures of preventive medicine and health promotion.
2. So to cooperate with the medical and dental professions that the services will be adequately provided when the demand arrives. This means in effect that the health organization must take the message of preventive medicine and health promotion to the practising physician and dentist to the end that they may become better able, willing and anxious to participate in this type of work.

The diphtheria prevention program in Detroit is in keeping with this policy. Having carried on clinics for diphtheria protection continuously for 8 years we felt that the value of this service had been well demonstrated. The majority of the people in the community had

FIGURE II

learned that diphtheria is a definitely preventable disease and that the means of obtaining protection is simple and harmless.

During the summer of 1928 a coöperative plan was worked out between the Department of Health and the local medical society whereby, beginning in October, 1928, the physicians of the city agreed to give all diphtheria prevention treatments and Schick tests. The physicians also agreed to sign for toxin-antitoxin and Schick material

taken from stations (the Department of Health established 8 stations from which these materials could be obtained day or night), and to report work done. Postal cards upon which the Department of Health would pay the postage were supplied for this purpose. There are two types of card, one for the Schick test and the other for toxin-antitoxin. The physician is asked to take from the station at which he receives his material the same number of toxin-antitoxin postal cards as he takes c.c. of toxin-antitoxin in order that each dose may be reported separately.

At first thought it would seem expensive and unnecessary to have a separate report for each dose given but it was felt, after discussing the matter with a good many physicians, that more complete and accurate reporting would result if the physician could merely write on a card the name of the child, address, age, and check the dose given, drop the card in the mail and forget about it until the next dose, rather than that he should be asked to keep record of the doses and report at the end of the series of treatments.

In the original plan of 1928, the physicians agreed to give diphtheria prevention treatments for a reasonable fee or free of charge to those unable to pay.

For its part, the Department of Health agreed not to give any toxin-antitoxin or Schick tests; but to carry on the educational propaganda necessary to give impetus to the work—news stories, paid advertisements, posters, lectures, radio talks, and the distribution of literature; to distribute toxin-antitoxin and Schick material and postal cards upon which reports could be made; to keep records of work done; and to reimburse physicians at the rate of \$.50 per injection of toxin-antitoxin or \$1 for the Schick test for work done for patients unable to pay.

FIGURE III

This, then, was the plan in 1928. Certain mistakes were made at that time which have since been rectified. For example, in the original program the medical society pledged the physicians of the city to the agreement and all physicians were given written notice of the agreement and plan but only a comparatively small number of them were actually seen and talked with concerning it. The result was that many physicians did not know the details of the plan, except as they may have read it in the letter which was sent them, and probably many of them did not even read it, and not being familiar with it were not entirely in sympathy.

During this first year of the program, children were sometimes referred to physicians who did not believe in diphtheria protection and in some instances they got into the hands of physicians who charged exorbitant fees. While such instances were not especially numerous, they did mitigate against the success of the program. We (that is the Department of Health and a small group of influential and prominent members of the local medical society) were deluded into thinking that we had "sold" the idea to the medical profession as a whole, when as a matter of fact only a small percentage of the physicians of the city knew much about the plan. It is only human nature for an individual to be against a program about which he knows little or nothing.

With the conviction of this error in mind—and this error is, by the way, the one most commonly made in attempting coöperative programs with the medical profession—in 1929 a letter was sent to each physician of the city asking whether he cared to coöperate in the diphtheria prevention program. If he agreed he was asked to fill out a questionnaire, which was enclosed with the letter, and return it to the Department of Health.

As an immediate response to this letter, approximately 700 physicians signed the questionnaire indicating their willingness to accept children for diphtheria protection, at certain hours specified by them, for \$1 per dose or free of charge for all those unable to pay. Since the original letter, the number of coöperating physicians has grown to nearly 900, which represents approximately 85 per cent of the total number of physicians in the city who might be in a position to participate actively in diphtheria prevention work.

In spite of the fact that the plan had been presented in detail in writing and that each physician had signed a written agreement to participate actively in the program, we nevertheless realized the necessity for having personal contact with as large a number as possible. Accordingly we took every opportunity of addressing meetings of medical groups. Not only was the local medical society itself addressed

Address

Regular Office Hours: A.M. from to Special Diphtheria Day

P.M. from to

Mon. Tues. Wed. Thurs. Fri. Sat. Sun.
(Please check day set aside)

Hours from to

..... to

In order to help wipe out diphtheria, I agree to administer 3 injections of toxin-antitoxin in my office for the following fees:

I will set aside special hours day a week (as noted above) for toxin-antitoxin injections, charging for each such injection during those special hours a fee of \$1.00.

If I cannot set aside special hours for toxin-antitoxin injections, I am willing to give the injections during my regular office hours at a rate of \$1.00 for each injection of toxin-antitoxin.

Be sure to designate clearly the day or days and hours during which you will be willing to accept patients for toxin-antitoxin and Schick tests

I further agree to immunize such children whose parents cannot afford to pay for such service, free of charge to them. For such service, upon receipt of proper statement, the Department of Health agrees to reimburse me at the rate of \$.50 for each injection of toxin-antitoxin and \$1.00 for the Schick test including its reading.

I consent to the inclusion of my name in a list of doctors who, as an additional contribution to public health, agree to administer toxin-antitoxin for the above fees. This list is to be used by the Health Commissioner, or the Wayne County Medical Society, or others designated by them, for the purpose of directing parents who are not attached to regular doctors and to encourage those who can pay for their medical service to do so.

I further agree to sign for all toxin-antitoxin and Schick test material taken and to make report to the Department of Health on use made of it on post cards provided for this purpose.

Date Signed M.D.

P.S. Failure to receive word from you will be assumed to indicate that you do not care to have your name included among those coöperating in the Diphtheria Prevention Campaign.

*The Public Health Committee of the Wayne County Medical Society
coöperating with the Detroit Department of Health*

(Use Other Side for Any Comment)

on diphtheria prevention, but short talks on the subject were also given at several successive meetings of each of the branch medical societies.

Advantage was also taken to present the subject at hospital staff meetings. In addition three separate meetings were held to which the coöperating physicians were invited. These meetings were held at our own hospital and refreshments were served. At each meeting the plan was discussed in detail and changes made in accordance with sug-

gestions received. The Schick test was demonstrated and a number of children, who had been Schicked, were present to permit reading of the test. In all, about 260 of the 700 coöperating physicians (there were 700 at that time, there are now about 900) came to one or another of these meetings.

In 1930 arrangements were made for a large series of neighborhood meetings in which one physician invited ten or a dozen of his colleagues in the neighborhood to come to his house or office to discuss plans for greater participation on the part of the practitioner of medicine in the field of preventive medicine and health promotion. A definite and carefully worked out program with clinical material for demonstration was presented at each of these meetings. It is our belief that some such system as this is the only feasible means of bringing about effective participation in the field of preventive medicine and health promotion on the part of physicians in urban communities pending the time that these subjects are more adequately taught in medical schools.

This, then, without going into too great detail, is the policy of diphtheria prevention which is being carried on in Detroit today. Perhaps even more encouraging than the actual results of the program to date is the attitude of that group of physicians who have been most closely associated with the plan. This group has shown not merely an interest but a very enthusiastic active interest in diphtheria prevention and in the entire field of public health.

What have been the results and what do we hope eventually to accomplish?

Beginning in 1921, diphtheria protection was given in schools to those children whose parents were willing to have them protected. In spite of the fact that diphtheria was high that year, only a few children were immunized, as might be expected, for long time protection against diphtheria was at that time a relatively new thing to the public. This same program of giving diphtheria prevention in schools was carried on through the year 1925 with gradual increases in the number of children immunized. In 1926, diphtheria became unusually prevalent and much of it was of a very severe type.

In that year the Department of Health not only carried on its work in the schools but also opened 18 free clinics in strategic parts of the city and launched an extensive publicity and advertising campaign. People were frightened and the number of immunizations rose to 106,000, the largest number to be protected in any single year. It is interesting to note that during the next year, 1927, with diphtheria far less prevalent but with the same number of free clinics and with an equal, if no greater, expenditure of funds and effort devoted to pub-

FIGURE IV

licity and advertising, the number dropped to 38,800, only slightly more than one-third the number immunized during the preceding year. There was a still further drop in numbers protected during 1928.

In the fall of 1928, the present plan of having all the work of giving diphtheria preventive treatments and Schick tests done by the practising physicians was instituted. We have already pointed out some of the mistakes that were made at the inception of the plan, and the methods by which we have attempted to correct them. Numbers protected during the first two years of this program were not great but in 1930 the number protected exceeded 50,000, which is the greatest number reached in any year except 1926, when diphtheria was unusually prevalent and severe.

The increase in numbers protected in 1930 may be attributed principally to two factors: (1) A thoroughly awakened interest on the part of the physicians of the city to have children protected against diphtheria, and (2) a change in method of persuading parents to have their children protected. The increased interest on the part of physicians is due to the fact that an ever increasing number of them are becoming thoroughly familiar with and, therefore, sympathetic toward the program.

The year 1930 saw a decided change in the method of persuading parents to have their children protected. From 1921 through

1925, diphtheria prevention was undertaken only in the schools and most of the children reached were of school age. Notices were sent home to parents asking permission to immunize their children, but no extensive publicity campaign was carried on. In 1926 and from that time on, increasing emphasis was placed on the necessity for having preschool children protected. From 1926 through 1929, a very extensive publicity and advertising campaign was in operation. It may be well, at this point, to differentiate between a diphtheria prevention program and a publicity and advertising campaign. Our program for protecting children against diphtheria is a continuous one, going on throughout the year and from year to year. Publicity and advertising campaigns, on the other hand, are carried on for short periods of time, usually in the fall, to give impetus to the work of diphtheria prevention.

Publicity and advertising include news stories, paid newspaper advertisements, outdoor bill boards, posters in street cars, stories in foreign language and neighborhood papers, moving pictures, lectures, radio talks, and the distribution of literature on the subject. Pamphlets are distributed through schools, clinics, meetings, and are also enclosed with birth registration certificates. When a child reaches 6 months of age its parents are sent a letter advising immunization against diphtheria.

These intensive publicity and advertising methods succeed in arousing a certain group of the population to definite action. Children of parents in this group have, for the most part, been protected as a result of these publicity methods. There is another large group of individuals (whether this group is larger in Detroit than elsewhere we have no way of knowing, but it is in any event a large group) who cannot be aroused to action through the generally accepted channels of publicity and advertising.

In an effort to reach this group effectively, two rather large districts of the city in which diphtheria had been unusually prevalent and severe (the two districts comprising 18.3 per cent of the city's population had, in 1929, a total of 26 per cent of the city's diphtheria cases and 31 per cent of the deaths) were selected for an intensive house-to-house canvass by public health nurses, the object of which was to secure the immunization against diphtheria of children between the ages of 6 months and 10 years. This work was carried on during the summer of the present year, 1930. An average of 45 nurses devoted their entire time for 2 months to this project. So encouraging were the results (in all 62.57 per cent of the children whose parents were interviewed in those districts are now protected against diphtheria or

rather have completed their series of diphtheria prevention treatments) that it was decided to continue and enlarge this type of work.

In order to permit the enlargement of this project it was decided to postpone certain phases of health work that could be temporarily postponed in order to release personnel for diphtheria prevention work. The city was divided into 15 large districts (exclusive of those districts in which intensive work had already been carried on), and 112 nurses were assigned to diphtheria prevention work in these districts. This project commenced on October 20 and for the next 4 months these nurses devoted their efforts toward securing the immunization of all children between the ages of 6 months and 10 years. They called in all homes throughout the city where there were children of this age group. Coincident with this actual interviewing of parents the usual publicity and advertising were carried on.

One of the daily newspapers sponsored a diphtheria prevention poster contest in which the Department of Health purchased the three winning posters for use in the diphtheria prevention program. Posters were judged not on artistic merit alone but also on their ability to portray diphtheria prevention. In order to make the nurse's interview as effective as possible, each nurse has been provided with not only a set of instructions as to the mechanical means by which the work is to be carried on, but also with a little pamphlet entitled "Questions and Answers," which answers the questions commonly

TABLE I

asked about diphtheria protection, and a sheet of instructions for a "sales" talk on the subject. The slogan emphasized in all publicity and advertising was "Children Need Not Have Diphtheria." All correspondence of the Department of Health was stamped in red letters bearing this caption.

We have already shown the number of immunizations which were effected in each of the years since 1921. Starting with only 579 in 1921, the numbers increased to a high point of 106,000 in 1926, fell off again and reached a second high point of over 50,000 for 1930.

The changes in age distribution of children protected are interesting and significant.

To summarize very briefly, it is our opinion that the program of having the private practitioners of medicine give diphtheria prevention treatments has a number of distinct advantages over the method of having this work done in schools or clinics.

1. The policy is in keeping with the average American's desire to choose his own grocer, his own clothing and his own physician.

2. It tends to place the responsibility, for that particular phase of child health at least, in the hands of the parent where we believe it rightfully belongs.

3. It makes a substantial beginning in attaining the goal toward which we are aiming: a greater degree of participation on the part of the private practitioner of medicine in the field of preventive medicine and health promotion.

4. It has a cumulative educational effect on both patient and physician which does not obtain in the clinic system. For example, if in the immunization of 50,000 children by private physicians we have created even as few as 2,000 new contacts between family and physician, which contacts become enduring, and the physician becomes the family health adviser, we will have accomplished something of far more reaching effect than the immunization of 50,000 children against diphtheria, important as that is.

5. This system seems to result in the immunization of a larger percentage of the most susceptible age group, the preschool child.

Newer Knowledge on Botulism and Mussel Poisoning^{*}

K. F. MEYER, PH. D.

San Francisco, Calif.*

SINGLE or group intoxications due to the ingestion of the toxin generated by *Cl. botulinum* and *parabotulinum* in various articles of food continue to be reported. With the exception of the annual reviews published in the *Journal of the American Medical Association*,¹ no statistical data have appeared on the subject of botulism since 1922.² It may therefore be of interest to review briefly some of the data collected during the past 10 years. In Table I the annual distribution of botulism is summarized.

In this connection it must be pointed out that no claim for completeness can be made on account of the well known fact that inquiries instituted in the course of the investigation of an outbreak of food poisoning not infrequently elicit histories of similar occurrences which have taken place in the same community or vicinity several years before. Unfortunately, botulism is only reportable in 13 states (Arizona, California, Colorado, Connecticut, Idaho, Kansas, Maryland, New York, Minnesota, Oregon, Washington, West Virginia, and Wyoming. Single cases, or intoxications, only superficially studied by a coroner's department may be due to the ingestion of botulinus toxin, while reports of such cases have been given as due to botulism on insufficient evidence. Complete data on this disease are therefore not available.

For a number of years, particularly during 1926-1927, few authentic cases of botulism were reported, largely due to the after-effects of the flood of publicity which called attention to the possible danger inherent in inadequately sterilized or preserved, especially home-canned, food products. During the past 2 years, a definite increase has been noted and group intoxications involving 5 to 12 cases have again made their appearance. As a whole, people who could probably

never be reached by any method of warning have been the victims of their own ignorance. With the exception of 2 cases of botulism traced to shalots (*Muscari commosum*) packed in Italy, home preserved vegetables, fruits, fish, and meats have been the products responsible. Commercially preserved food has not been connected with any of the recognized cases of botulism since 1925. Scientific canning procedures have replaced empiricism in practically every branch of the industry which packs products liable to botulinus spoilage. In the very near future, every type of food which is preserved by canning will either be subjected to such sterilization times and temperatures or to such processes of acidification and curing that the toxicogenic anaerobe will either be destroyed or its growth completely inhibited. Continuous vigilant supervision and far reaching education have been responsible for the removal of the botulinus menace from the commercial packing industry. The fundamental studies which enabled the industry to

apply scientific principles to the control of botulism have been published in a series of papers.³

The 191 single or group intoxications, collected over a period of approximately 30 years, involved a total of 625 people with 411 deaths. The case mortality rate has risen from 61.7 per cent in 1922 to 65.7 per cent in 1930. This exceedingly high rate is only surpassed by the figures (67.3 per cent) reported by Zlatogoroff and Soloviev⁴ for the fish poisoning cases due to *Cl. botulinum* in Russia. The average mortality of the German mass intoxications, with the exception of 3 instances in which home-canned string beans were responsible, has remained approximately 20 per cent. These differences may be due partly either to the low toxicogenic properties of the non-proteolytic *Cl. botulinum* Type B, or to the nature of the foodstuffs involved in the intoxications. The moisture in the causative food is doubtless an important factor. The high mortality in the American string bean group intoxications finds its analogue in the fatality rate of the German vegetable poisoning cases reported by Landmann, Blumer and Wagner.⁵ Meat and fish products with a high water content, in the form of pastes, soft sausages of the mettwurst variety, pickled fish, etc., have caused a higher mortality than hams or other relatively dry pork products in which the poison is unevenly distributed. Since approximately 88 per cent of the intoxications observed in the United States are caused by vegetables of various sorts preserved in brine, the possibility of ingesting a fatal quantity is considerably greater than in Germany where hams are the chief botulinogenic foods. Heat preserved canned foods are responsible for less than 5 per cent of the German botulinus intoxications.

As a rule the provisional diagnosis of botulism has been made without any difficulty, but it is noteworthy that the accuracy of the findings has only been confirmed by bacteriological tests in one-third of the observations. Attempts to determine the true nature of the poison doubtless have been made, but only too often the causative food either has been completely consumed or the remnants have been destroyed or discarded. In a few instances the clinical records have been confirmed by the demonstration of botulinus toxin in other containers of the same pack or the coincident occurrence of botulism in chickens.

The geographical distribution of the American outbreaks has changed only slightly. The rural sections of the western states (California, Washington and Colorado) continue to furnish the bulk of the observations. It is of interest that New York, with 10 single or mass intoxications, has taken 4th place, while such states as Oregon,

Idaho, Montana, North Dakota and Wyoming have recently contributed their share to the botulinus statistics. The data are in many ways interesting but it is here merely pointed out that botulism cases may be found with equal frequency in the eastern states provided an effort is made to investigate the distribution more carefully than has generally been the case.

The spores of *Cl. parobotulinum* are in the soil throughout the United States, England,⁶ Germany, and France,⁷ and have recently been demonstrated in specimens of mountain dirt collected from shalots in Southern Italy. In the light of the observations made in South Africa and of the findings reported by Kempner and Pollack⁸ many years ago, it is not unlikely that certain varieties of the botulinus group (non-ovolytic *Cl. botulinum* Types B, C and D) lead a saprophytic existence in the intestinal canal of animals, as, for example, in hogs. Fecal and not soil contaminations may, therefore, confer on the food the dangerous botulinogenous properties.

The rather frequent occurrence of these varieties of *Cl. botulinum* in the bone marrow of cattle, lamziekte or hogs (the growth of spores in the marrow with diffusion of the poison through the foramina), lends considerable support to the interpretations of the few carefully studied observations. A search for non-ovolytic botulinus Types B and D in manure remains, however, futile until a selective enrichment medium has been devised. In this connection, it is recalled that the non-ovolytic Type C has been found in the United States but so far has not been connected with human cases of botulism. In all probability this is due to the fact that the toxin must be ingested in large quantities in order to cause intoxication in man. Type D has been isolated in South Africa and it is claimed that Types A and B are unknown in that country.⁹ The Van Ermengen B strains have not, as yet, been found in the United States. The examination of many thousands of samples of soil, sewage, manure, etc., of American origin has never furnished indication of botulinus toxin producing anaerobes which resemble these Van Ermengen strains. Notwithstanding these negative findings it is not safe to conclude that the bacillus is not present on the North American continent. It is highly desirable that the ecological studies on the botulinus organism begun many years ago be continued in order to establish more conclusively the genetic relationship of the Types A, B, C and D.

In Table II the foods proved to be responsible for the 192 outbreaks are briefly summarized. Plant products were involved in 72 per cent of the cases, while 18 per cent of the outbreaks must be attributed to animal products. Home-canned string beans continue to

play a very important rôle, largely due to the well known fact that spoilage of this vegetable when preserved is so slight that the housewife or cook will often fail to detect it. Furthermore, string beans are frequently served as salads and any odor which might arouse suspicion is usually masked by the vinegar or mayonnaise dressing. Home-canned corn has also been a frequent offender.

Occasionally the monotonous character of these intoxications is changed by the occurrence of an observation in which an article of food rarely connected with botulism is a carrier of the deadly toxin. Plant or meat products supposedly immune from botulism spoilage have recently been definitely associated with fatal cases. Invariably the article of food was improperly preserved, that is, either under-processed or inadequately acidified. The factors responsible for the spoilage in Bartlett pears by *Cl. botulinum* have been studied." It has been demonstrated that *Cl. parobotulinum* may generate and

elaborate a deadly poison in the cooked fruit irrespective of the acidity, provided certain bacteria or yeasts are growing concomitantly.

The observations of the past 10 years leave no doubt that all canning methods, whether commercial or home, should aim at absolute sterility of the product to insure freedom from *Cl. botulinum* or *Cl. parobotulinum*. In case this prerequisite cannot be met, acidification with citric acid, or with a mixture of acetic and citric acids, to a pH of at least 4.5 with subsequent heating of the product at 100° for a short period, should be practised. Such vegetables as artichokes, chilis, mushroom sauces, etc., can now be well preserved by the procedure of acidification.

From a public health standpoint it is imperative that the principles developed by the canning industry be applied to the methods of home canning. A vigorous, systematic program of continuous education may in time reduce or eliminate the many unnecessary deaths from botulism.

MUSSEL POISONING

After the serious outbreak of mussel poisoning¹ in July, 1927, in San Francisco and vicinity, in which 102 people, with 6 deaths, were involved, the problem of this intoxication was assigned to Dr. H. Sommer and his assistants. The question which deserved primary attention was to ascertain the time of year and the locality along the coast where the mussels would again be expected to become dangerous for human consumption. For this purpose a standard animal test which enabled the workers to examine mussels at frequent intervals was developed.* The result of the periodic examinations proved definitely that the Pacific Coast mussel (*Mytilus Californianus*) collected at various places from Monterey Bay in the south, to as far north as the mouth of the Klamath River, may contain a small amount of typical mussel poison at any time of the year.

To date very few samples have been tested outside of this area and therefore no definite conclusions can be drawn relative to the frequency of non-fatal doses of mussel poison in this shellfish in Southern California. Since mussels are consumed in large quantities without ill effects by the population along the coast, it is reasonable to conclude that the "slightly" toxic mussels are not important from the standpoint of public health.

During the months of July and August invariably the mussels become highly toxic and dangerous for human consumption. In 1928 "moderately" poisonous mussels were found from July 20 until Au-

* To be published.

gust 9 in one locality 50 miles south and in another 50 miles north of San Francisco. No human cases occurred during this season. The mussels collected between July 10 and August 14, 1929, from Pescadero to the mouth of the Russian River proved "moderately" to "very strongly" poisonous. These findings were promptly paralleled by the occurrence of 56 human poisoning cases between July 7 and August 6. Fortunately, only 1 of the intoxications proved fatal.

The outstanding observation of the 1929 outbreak of shellfish poisoning was, however, the occurrence of the cases of August 4 which were due to the eating of Washington clams. Three of the cases proved fatal. Subsequent animal experiments on clams showed that 7 of the 8 varieties examined were highly toxic, and especially the 2 large species, *Saxidomus nuttallii* (Washington clam) and *Schizothaerus nuttallii* (Horseneck clam), which contained a large amount of poison. The clinical observations as well as the laboratory findings indicate that the clam poison is a substance very similar if not identical with that of the mussel.

In midwinter, 1929-1930, "moderately" toxic mussels were collected north of Bodega Bay, and again in March, 1930, at Point Reyes. The latest findings during the summer of 1930 are entirely in accord with the experiences of the past 3 seasons. The mussels reached a degree of toxicity designated as "moderate" to "strong" from July 8 until August 22, with a maximum of "very strong" on July 26 near the mouth of the Russian River. On July 27 1 human case of mussel poisoning occurred in that vicinity. Of the clams tested *Saxidomus nuttallii* contained a small amount of toxin. The beds from which the mussels were gathered are all exposed to the open shore line subject to the ebb and flow of the tides, and, with one possible exception, never exposed to pollution by sewage. It is therefore noteworthy that in the course of the investigations it has repeatedly been demonstrated that the mussel poison cannot be detected with certainty in the San Francisco Bay mussels (*Mytilus edulis*) nor in the clams (*Mya arenaria*) of the same region.

In a score of other mollusks, echinodermata, and miscellaneous specimens collected in the vicinity of the mussel beds of the coast, no definite shellfish poison was demonstrated, although many of the samples exhibited a harmful action on the test animals. Toxic extracts with properties distinct from mussel poison have been obtained from fish eggs (crotus), starfish and chitons (*Mopalia muscosa*). These investigations required a special procedure.

The wet, dry and skeleton weight of the various shore animals had to be estimated, and the toxicity of the various solutes of sea water had

to be investigated since poisonous magnesium salts seriously interfered in the animal experiments when the extraction of the marine material was not carefully controlled. Numerous observations indicate that the mussels under water are often more toxic than those found above the mean water level. The maximum toxicity seemed to occur soon after or during the maximum tides of the year. In July and January, epidemiological as well as laboratory studies tend to indicate that the factor which renders the mussels poisonous begins to operate south of the Golden Gate and travels north. The influence of oil formation, influx of detritus, unusual odors, luminescence, turbidity and color of the water, changes in temperature, etc., have been recorded. However, their connection with the phenomenon of mussel poisoning has not as yet been successfully established.

The toxic mussels may have a typical odor of cyanide which in most cases is, however, very faint. The hepato-pancreas of the harmful shellfish usually is larger and softer and is often of a greenish color, lighter or darker than the normal digestive gland. Experience has shown that these anatomic and metabolic changes may allow a differentiation of the innocuous from the harmful specimens.

In most cases the occurrence of mussel poisoning coincided with the spawning season although the two phenomena do not run strictly parallel. *Mytilus Californianus* has been found to spawn in mid-summer, in midwinter, and in certain localities during the spring. At least in the San Francisco Bay region the mussels pass through two spawning seasons during the year, and detailed histological examinations of toxic and non-toxic mussels have not revealed any consistent differences, though the studies are still in progress. In this connection a study of the sea water in amounts up to 3,000 liters was undertaken. The water was filtered and the plankton examined and tested for toxicity. During, as well as before and after, the toxic period, micro-organisms of the ocean water were found to contain neither shellfish poison nor other similar toxins.

Attempts to produce poisonous mussels by exposure, suffocation, etc., at various temperatures in and out of sea and fresh water have thus far failed. A slight formation of poison may take place when mussels are treated with illuminating gas. Cyanide is without effect on the toxicity of the mussels. The ability of shellfish to store poisons has repeatedly been demonstrated, particularly in experiments with strychnine.

Preliminary pharmacological investigations with a purified shellfish poison have given the following prominent results: Slowing of respiration after small doses; violent dyspneic movements, and respira-

tory failure after injection of lethal doses. The action on the blood pressure is complex and consists in general of a depression followed by a secondary asphyxial rise. The initial effect on the heart rate is characterized by an increase with subsequent slowing of the beat. The heart continues to function slowly after respiration has stopped. The poison is rapidly excreted through the urine (30 per cent in 2 hours). Amiodoxyl does not oxidize the poison *in vivo* or *in vitro*. Injections of caffeine rather hasten the death caused by shellfish poison, probably on account of the increased rapidity of absorption.

As a precaution against occurrences of mussel poisoning, the State Department of Public Health regularly issues a warning against the use of mussels during the period when they are particularly liable to be dangerous. Their sale has been forbidden during the past 2 summers. The quarantine is only lifted after repeated tests of numerous mussel beds have shown that the mollusks are "slightly" or non-toxic.

Diphtheria Prevention on a State-wide Basis and the Part the Public Health Nurse Has Taken*

MARION W. SHEAHAN, R. N.

*Assistant Director, Division of Public Health Nursing, New York State
Department of Health, Albany, N. Y.*

WHO shall say where or how the best toxin-antitoxin campaign has been developed; and would such a statement help the further development of the project to any great extent? We have chosen to outline certain experiences in developing toxin-antitoxin campaigns in New York State, because that is the territory with which we are most familiar.

The diphtheria prevention program on a state-wide basis became a joint major activity of 5 state-wide official and nonofficial organizations in January, 1926, and has remained so for 5 years. The New York State Department of Health provided official direction and organization service and advice through its field workers, and supplied toxin-antitoxin mixture free to local health departments and to private physicians. The State Department of Education secured the interest of local boards of education, of school medical inspectors, of school nurses and school teachers, and issued a statement to all parents and all school authorities asking their help to eradicate diphtheria.

The Metropolitan Life Insurance Company through its Welfare Division gave financial support, supplied a huge amount of excellent free literature, moving picture films, statistical service, and special speakers both for radio broadcasts and for local groups. The company solicited the active participation of its field agents, local district managers, medical examiners and visiting nurses. The State Committee on Tuberculosis and Public Health of the State Charities Aid Association put its long years of experience in health promotion through local organization to work. Practically every medium of popular health education was utilized to secure public support and to bring the various official and voluntary agencies together for a concentrated attack on diphtheria.

* Read at a Joint Session of Child Hygiene, Public Health Education, and Public Health Nursing Sections of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

The State Medical Society sent an announcement of the purposes of the campaign to every physician in the state; while the President and the Executive Officer personally visited local medical groups to stimulate and plan for their part in the program. Nearly every medical society in the state endorsed the project and some took an active part in local campaigns.

The work of all these agencies was directed and coördinated by an Executive Committee composed of representatives of all participating agencies. The committee held monthly meetings to formulate plans, direct organization and publicity, and to appraise results. With this pooling of the efforts of the parent organizations the diphtheria prevention campaign was started.

The result was the almost immediate awakening of local interest to the extent that the health departments and local health agencies of many up-state cities and towns immediately placed diphtheria prevention through immunization as one of their major activities.

As a logical development of the type of organization of the state-wide movement, local organizations followed somewhat the same plan with variations to fit local needs. In a community where the greater proportion of children is unprotected, the problem is to find the most effective way of securing the immediate immunization of a sufficient number to affect the incidence of diphtheria. The campaign method has proved its value in this respect; what will come later to secure continuous immunization is another question.

PLAN OF CAMPAIGN

The type of local campaign which has found most favor, judging by the frequency of its use, is the short intensive drive which aims to place diphtheria prevention in the center of the stage for a brief period terminating in large immunization clinics. The local health officer is responsible for the work. He secures the active aid of representative people; representatives of agencies, official, semi-official, and private, of the press, church and school, all of whom give actual help and lend prestige to the work. Sub-committees are formed each with a definite job. Thus the work of publicity, education, house-to-house canvass, finance, transportation and clinic assistance is taken care of.

The territory is divided into districts for ease in handling, but the work is carried out simultaneously in each district following the plans mapped out by the central committee. Besides the usual kind of publicity, all types of spectacular publicity stunts are used to create a public consciousness regarding the situation in such a way as to stimulate immediate action from the parents of children. House-to-

house visits are made by informed workers; usually volunteer lay people with the help of public health nurses, who interpret the subject to the parents and endeavor to secure a signed request card which is a promise that the children of the family will be taken for immunization either to the family physician or to the clinic. Subsequent follow-up of delinquents is carried on.

The campaign is terminated by the holding of large clinics at which all children who bear consents from their parents are immunized. The clinics are continued usually 5 or 6 weeks to take care of those who failed to appear but who may be brought in through the follow-up by public health nurses. This follow-up is of utmost importance and upon its thoroughness will depend to a large extent the success of the work.

RESULTS

The results that have been obtained from such campaigns can be judged by a brief statement of the accomplishment in some of the communities where a campaign has been conducted with an energetic follow-up program. Middletown has succeeded in immunizing about all its school children, and in 1929 reported protection in more than 70 per cent of those under the age of 5; Ogdensburg over 60 per cent; and Mamaroneck over 50 per cent of this lowest age group, in addition to a protected school population. Utica started a community campaign in February, 1927, and by July reported that the number of immunized children had increased from 38 to 68 per cent of the 5-9 age group and from 9 to 29 per cent of the under 5 age group. In the city of Niagara Falls an intensive campaign was started in March, 1928, and by the end of May the reports showed an increase of immunized children of the age group 5-10 from 67, which was the 1927 figure, to 95 per cent, and in the lowest age group from 8 to 43 per cent.

These figures serve to prove that this type of intensive campaign does produce the results desired in initiating a diphtheria prevention program, and if well directed will secure the immunization of a sufficient number of children both of the school and preschool group to reduce the morbidity and mortality from diphtheria in a given community.

THE PART OF THE PUBLIC HEALTH NURSE

The public health nurse has taken her part to help obtain these results. She usually becomes one of the official assistants of the health officer, who helps to interpret the plans to coworkers without

the health department. She does her share in instructing lay workers, receiving their reports, smoothing out difficulties, giving advice; and she follows up the parents who have been reported uncoöperative by the lay home visitors. She is usually responsible for the physical arrangement of the clinic rooms, for the details of clinic preparation, for assigning untrained helpers to the work they seem best fitted to do. The work she does during the campaign, however, is only incidental to her greatest contribution, which will be mentioned later.

CAMPAIGN EXPERIENCES

The early experiences of several communities where the first intensive campaigns were conducted demonstrated 3 important facts:

1. It was unnecessary to have a diphtheria epidemic to awaken public interest.
2. This interest could be a substantial one consisting of willingness to canvass, to lend and drive automobiles, and to perform clerical and other services in assisting at clinics.
3. A brief campaign of preparation was equally if not more effective than a long one.

These facts are important enough to bear discussion. The first one answers a controversial question. Many experienced public health workers have felt that the interest of the public cannot be awakened to the point of individual action unless the point in question has "struck home." This is true to a certain extent as is demonstrated by the fact that many more immunizations are secured when home visits are made to interpret to the parents the personal application of the problem which has been called to their attention through the channels of publicity. However, the evidence is that a striking individual or community situation need not be the basis for successful appeal; it can be made on the ground that it offers a necessary health measure to safeguard the children of a community. This point may be more pertinent to the situation in up-state New York because the first city-wide immunization campaign, which was a demonstration, was carried out in Auburn where diphtheria mortality and morbidity rates were high. The splendid success of the work in Auburn was thought by many to be due to the fact that diphtheria presented a community problem out of which capital was made in securing effective immunization. Numerous experiences have proved conclusively that such a local situation is unnecessary.

The second point is history repeating itself. We have many examples of concerted action for a worthwhile cause where all hands pull together under direction to accomplish a definite purpose. An experienced leader, a well thought out plan, careful definite instructions to workers, and a time limit, are the requisites necessary.

The third point is a good one to remember where volunteer workers aid in carrying out a big project. Their time will be generously given for short periods but cannot be drawn on indefinitely. The thrill of speedy returns to which all humans respond provides the driving power to keep volunteer help on the job. Much can be said in favor of steady dogtrotting methods, but whatever their merits, they have no place in the plan of work we have been discussing.

Another type of campaign was carried out in the city of Schenectady, initiated and sponsored by the County Medical Society. A physician was employed on part-time to supervise the work, and the services of a clerk provided. The plan was to interest the medical profession of the city and to hold the profession responsible for the immunization of the preschool population. The hope was that the physicians would make immunization a part of their routine practice to such an extent that continuous immunization would be carried out. Indigent parents, who are said to represent a very small percentage of the people of that community, were to take their children to public clinics. It was thought that immunization clinics were unnecessary except for indigents and that most people would prefer to go to their family physicians and pay for their services. The city was divided into districts and the Health Department gave its nursing service to make a house-to-house canvass. The nurses were to return card reports of consents, on which was to appear the name of the family physician. Any person claiming to be unable to pay was offered the alternative, on certification of the nurse, of going to his family physician gratis or going to a free clinic to be held later. Publicity was carried on through the usual channels. This method of campaign was continued for nearly 3 years and ended January 1, 1929.

The results were not all that the Medical Society had hoped. While it succeeded in securing about twice as many immunizations of children under 5 as of children 5-9 years old, the total of immunizations was too small to insure a community protection against a considerable increase or an epidemic of diphtheria. Whenever the nurses, for one reason or another, ceased to canvass, there followed a decline in the number of reported immunizations, indicating that the physicians of themselves apparently had not been securing a large number of immunizations. The cost of bringing a child to the family physician or to a clinic for immunization was \$2, exclusive of the salary and expense costs of the nurses engaged in carrying on the canvass. This was also exclusive of the physician's fee. In no other community was such a cost even approached.

The campaign failed also to develop a community immunization

consciousness or to secure the participation of unofficial organizations. As a consequence the local health department at the end of the campaign faced the same situation which other communities faced at the beginning of 1926, and has made little recent progress.

Another plan attempted in a small community is interesting. A county public health nurse, with the advice and approval of the health officer, called up the physicians of the community and offered to visit the families of their patients where there were children, to explain to them the need for diphtheria immunization and to urge them to go to their family physicians on a certain day which they would designate. She offered her assistance to them for this "office (pay) clinic." Supplies could be secured in advance and the "fussing for one child" process would be eliminated. For some reason the physicians hesitated to accept such help even though they thought the scheme would work; so it fell through without a trial. Such a plan might hold possibilities for further experiment and might be very successful for small communities if sponsored by good community organization.

Other experiences could be mentioned but they would be to a large extent variations of the plans above outlined. The test of any campaign is whether or not it results in a number of immunized children of both the school and preschool age groups sufficient to eradicate diphtheria from the community. The importance of protecting the preschool age group cannot be too strongly emphasized. Many communities in the early days of the campaign followed the line of least resistance and thereby immunized a very small percentage of the preschool group. A study of their records for diphtheria morbidity and mortality proves without doubt that a community will only be protected from diphtheria when 25 to 30 per cent or more of the lowest age group is immunized, perhaps in addition to the school population.

There are many factors to consider in planning a campaign which will reach the objective with the least waste of time, energy and money. The magnitude of the problem should be judged by determining how many unprotected children there are in the community. The method of approach should be determined by the character of the community, the financial status of the people, the average intelligence, the racial make-up of the population, the influence of church and other organizations, and other factors peculiar to a community which will suggest themselves to one familiar with a local situation. Thought should be given to the right of the medical profession and of other organizations—official, semi-official and private—to participate in a community undertaking of such vital importance.

After 5 years of experience in our state it is possible to outline

with some degree of assurance the steps for a successful community campaign of diphtheria prevention through immunization.

The plan should provide for:

1. Concerted community action through utilization of the prestige and help of medical profession, of official, semi-official and private organizations, of representative lay people, of church, schools and of press
2. Adequate publicity to awaken community consciousness to the problem
3. A preliminary house-to-house canvass and subsequent follow-up of those who failed to respond
4. Adequate clinic service
5. Careful record keeping and appraisal of results
6. A follow-up program to secure continuous immunization of infants at 6 months of age

The above plan is not offered as the best one by any means but, given good leadership to adapt it to a local situation, it has proved its possibilities for success in initiating a diphtheria prevention program in a community. After public opinion has been created and after the first big job of immunization is over will come the part of the task that will insure continuous protection to the child population. It is for this task the public health nurse will make her greatest contribution. This is rendered day in and day out through her ability to reach the parents in the community, and to interpret to the parents the reasons for immunization in language they will understand. She may be aided by occasional intensive campaigns and by constant publicity; but in the long run as long as she holds her place as the most effective home visitor in the public health field, health authorities will depend on her skill in persuasion, on her effective teaching to secure continuous immunization of each year's crop of babies. A community cannot hope to safeguard its children from diphtheria permanently unless it expects such service from its public health nurses and sees to it that the results are obtained.

One health officer in a town where the average number of births is 300 a year has told the public health nurse he expects her to secure an average of 30 children for immunization each month. The campaigning is over and the work must go on. In fulfilling that requirement the public health nurse is taking her part in insuring her community against diphtheria.

POSTVACCINAL ENCEPHALITIS

SINCE the days of Sir Edward Jenner, vaccination against smallpox has held its own as one of the greatest preventive measures ever discovered. It has been attacked on various grounds, religious and otherwise, but the world has accepted and practised it to the great benefit of mankind, and the saving of human life.

The mistake of holding that a single vaccination protects throughout life has been generally made. Waterhouse, 1799, said: ". . . A person who has undergone the local disease and specific fever occasioned by the cow-pox infection is thereby rendered ever after insusceptible of the small-pox." We have pointed out this fallacy in these columns and urged vaccination and revaccination, statistics in armies and other bodies where control is complete showing the value of this procedure as against the single inoculation.

A new factor has recently appeared. We were startled a few years ago by the appearance of encephalitis following vaccination. In Holland the cases were comparatively numerous, but at worst, they were small in number compared to the total number of vaccinations, though they led to a temporary suspension of vaccination. Cases were reported from England, and a few from other European countries. Our Public Health Service has been awake to the situation from the beginning, has made extensive studies, and kept close watch on developments. Altogether, some 57 cases of encephalitis have occurred in

America during the last ten years. In the light of the facts now known, what should the responsible physician recommend?

Ordinarily there is not the slightest ground for the omission of vaccination against smallpox. Exceptionally, it may be prudent to postpone it. Even if the number of bad results of which we are aware is smaller than the actual truth, still the procedure does vastly more good to society than harm. We have become so accustomed to the mild types of smallpox that many have grown careless. Sanitarians and physicians have warned people that the neglect of vaccination would be followed sooner or later by a return to the old virulent type in which the mortality was close to 50 per cent. This prediction has been verified in Kansas City, Detroit, Minneapolis, and Denver fairly recently. An analysis of the results of vaccination in many of these epidemics will convince all reasonable people that the disease was tremendously fatal in the unvaccinated, very slightly so in those once vaccinated, while the revaccinated were practically free from danger. Further, the epidemics were arrested in comparatively short order by vaccination. Within the memory of many living people the terrible experience of Montreal stands out against these favorable results.

So far from being afraid of vaccination we should urge it more than ever before, and recommend especially vaccination during the early months of life, before teething, since untoward results at this early age are exceptional. Revaccination should follow at proper intervals, especially in early life, and at school age, since smallpox is a disease of that period.

No human procedure is infallible. Health officers and physicians should arm themselves with the facts as to the occurrence of smallpox before the introduction of vaccination, and at the present time. We should acknowledge the very slight risk which attends the procedure. We can no longer tell people that it is entirely devoid of danger, but we can assure them that the beneficial results to the community far outweigh the danger. Further, there is some reason to believe that encephalitis following vaccination may be connected with the greater prevalence of epidemic encephalitis and poliomyelitis observed in several countries, and that with their decrease, postvaccinal encephalitis will also diminish.

After more than a century of experience under all conditions, we can unhesitatingly endorse the findings of the College of Physicians of London: ". . . that the public may reasonably look forward with some degree of hope to the time when all opposition shall cease, and the general concurrence of mankind shall at length be able to put an end to the ravages at least, if not to the existence, of small-pox," and the Re-

port of the National Vaccine Establishment: "The Board have infinite satisfaction in stating the two following important and decisive facts in proof of the efficacy and safety of vaccination, viz., that in the cases which have come to their knowledge, the small-pox after vaccination, with a very few exceptions, has been a mild disease; and that, out of the many hundred thousand persons vaccinated, not a single well-authenticated instance has been communicated to them, of the occurrence of a fatal small-pox after vaccination."

STANDARD METHODS OF COST ACCOUNTING FOR PUBLIC CLEANSING WORK

THE cost of street cleaning and collecting and disposing of garbage, ashes and other solid municipal wastes is now largely a matter of conjecture, so far, at least, as American cities are concerned. Nobody knows how much a city ought to pay for this service per capita or how much it does pay. Few, if any, keep records which attempt to cover the whole cost, including the work done by private scavengers, much less are able to report correctly on the cost of machine sweeping or of hauling or disposing of the wastes produced.

An attempt to standardize cost keeping in street cleaning and refuse collecting and disposition in American cities is being made through the Committee on Uniform Street Sanitation Records. This committee represents primarily the International Association of Public Works Officials, formerly called the International Association of Street Sanitation Officials. Other organizations represented in an advisory capacity include the National Committee on Municipal Standards, the International City Managers' Association, the American Society of Municipal Engineers, the Governmental Research Association, the American Society of Civil Engineers, the American Municipal Association, the American Road Builders' Association, the National Municipal League, and the American Public Health Association. The work is financed and staffed by the International City Managers' Association, through funds supplied by the University of Chicago and the Julius Rosenwald Fund.

The committee has issued what it calls a preliminary report and is now engaged in promoting a scheme of cost accounting based on certain standard work units which it proposes shall be universally employed in American cities. One of these units is called the "street cleaning mile." The theory is that distance rather than area is the important thing to record, the idea being that "the work is all applied in a lineal direction." The general custom up to now has been to consider the number of square yards cleaned as giving the best indication

of the work done. Again, the committee considers the cubic yard as the best unit of measure of refuse. At present custom is divided between the cubic yard and the ton. In the one case the quantity is usually estimated, in the second it is weighed.

The scope of the committee's work includes the results of all methods of sweeping and cleaning the pavements; catch basin cleaning; snow clearing and removal; garbage, ashes and refuse removal; removal of dead animals and night soil; and the ultimate disposal of the wastes collected. It does not describe how any of this work should be done. It does not include sewerage construction or maintenance, or sewage disposal, although this subject has much to do with street sanitation because of the part played by sewers in carrying off storm water and washings from the streets. The kind of pavement and its state of repair are not apparently allowed for although these have much to do with the sanitary condition of streets and the cost of cleaning them.

It is worth noting that the standards proposed do not take into account the dirtiness of the streets to be cleaned nor the degree of cleanness achieved. These would seem to be essentials, without which any records of efforts expended can have but little value.

"Installations" of systems of record keeping have been begun by the committee and the promotion of the ideas put out in the "preliminary report" is being actively pushed. In a recent press release the first complete installation of the records and cost accounting proposals of the committee is reported as made at Brunswick, Ga. A complete description of what has been begun there, with all the forms employed, is to be distributed to 800 other cities in this country. The committee explains: "This honor was accorded to Brunswick because it is performing all types of activities" included in the committee's program.

The idea of trying to put public cleansing on a businesslike basis, at least so far as reporting what is done goes, is worthy of all praise, and it is to be hoped that the committee has found a good way to make a start at it. It is a long step from the present state of the matter to the state of accountability aimed at by the committee and one cannot help wondering how many of the practical men in charge of this kind of work will willingly accept the forms and other proposals of the committee. How helpful such records can be in presenting a picture of what is done is not entirely clear.

Windsor Hotel, Headquarters of the A. P. H. A.

MONTREAL AND ITS PAST

ÆGIDIUS FAUTEUX

*Member of Royal Society of Canada, Librarian, Bibliothèque
St. Sulpice, Montreal, Canada*

IN this new world of America, there are not more than three or four cities which can boast of three centuries of existence. Montreal is quickly nearing that goal, having been founded in 1642. On that account, it is probably not out of season to cast on its past at least a rapid look.

Montreal was actually started in 1642, but if we are to measure the complete span of its history, we must go back to 1535 when the land on which it now proudly rises was trodden by the first white man, none other than Jacques Cartier himself, the discoverer of Canada. Undoubtedly, the famous navigator, while he was sitting among the Indians on the slope of Mount Royal, never dreamed that the round shaped village of Hochelaga would some day be changed into the immense agglomeration of structures we are now

witnessing, but he nevertheless marked for civilization the very spot on which he stood. The birth of the Canadian metropolis may be truly said to date from his landing at Hochelaga.

A little more than a hundred years, however, were to elapse between Cartier's first claim of Hochelaga as a new domain of the King of France and the actual planting of a city on the chosen land. During the interval, time has wrought many changes. In 1615, when Champlain, the second of his race, visited the site of Hochelaga, the Indians who greeted Cartier had already been driven toward some other country, probably by the misfortunes of war, and no trace even was left of their once prosperous village. The island had become a wilderness through which occasionally roamed migratory hordes of savage hunters. For some time again the only

white men who passed its shores were a few missionaries and hardy voyageurs headed toward the great lakes. Everybody of course was struck by the wonderful situation of the place but, in the infancy of the colony and with only a handful of defenders, there could be no thought of venturing the establishment of a post on a spot so far advanced and so extremely dangerous. To undertake such a daring enterprise at the time required more than the ordinary nerve of courageous explorers—it required the mystical enthusiasm of men who sincerely believed they answered a call from above. It is indeed remarkable that the foundation of Montreal was entirely and solely commanded by religious zeal. There was also more than a tinge of mysticism in the ad-

venture of the Pilgrims of Plymouth twenty-two years previously, but while the passengers of the Mayflower were actuated principally by a yearning for religious freedom, Maisonneuve and his followers thought only of the conquest of souls.

There is even a touch of supernatural flavor in the wonderful beginnings of the Canadian city. It is said that two pious gentlemen of France, who till then had never known each other, the priest Jean Jacques Olier and the layman Jérôme leRoyer de la Dauversière, had at the same moment a dream in which they saw clearly the configuration of the island of Montreal, although they had not known of it before, and heard an inner voice compelling them to establish a new colony for the furtherance of

Mount Royal is in the center of the city. It is a natural public park of 550 acres, 600 ft. above sea level. From this Look-Out on a clear day to the south may be seen the Adirondack Mountains, to the south-east the Green Mountains of Vermont, and to the east the Laurentian Range. At the base of the Look-Out may be seen the center of the city of Montreal, and the St. Lawrence River, also the harbor and the great canal system connecting upper lake transportation with the St. Lawrence River traffic.

1. Sturdy stone towers, built for defence against the Indians in Ville Marie's early days, standing in grounds of Montreal Seminary, Sherbrooke Street West. In one tower the pioneer nuns lived, in the other they taught the children of the settlement. 2. The wind mill and the outdoor oven are still used in Rural Quebec. 3. Chateau de Ramezay, erected in 1705, residence of the French and English governors of colonial Canada, and now a museum.

1. Panorama of Montreal showing Canadian National Victoria Bridge. 2. Royal Victoria Hospital is a monument to the generosity of Lord Strathcona, Lord Mount Stephen and J. K. L. Ross. 3. Montreal Harbor is owned and operated by the Canadian Government. It is a national port, and is managed by a special commission called the Montreal Harbor Board.

the glory of God. At all events, the two men providentially met in Paris and, after having by their joint efforts formed a society of no less ardent contributors, called "la Compagnie de Notre Dame de Montréal," succeeded in fulfilling their godly task. On May 18, 1642, the first settlers landed in Montreal, or, as it was then called, Ville-Marie. They were about 60 in number including half a dozen women. It was a very humble beginning for what was to become one of the large cities of the world.

The newcomers first busied themselves in building a roof which would shelter them from the rain and a palisaded fort which would defend them against the Indians lurking in the surrounding woods. The task before them was arduous, but they were fortunate in having as a leader a man whose bravery

was equal to his righteousness, a man whose name is revered to this day, and has never been tainted with the smallest blemish—Paul de Chomedy, Sieur de Maisonneuve. When pressed by Governor Montmagny to desist from his rash enterprise, this true Chevalier proudly answered: "Even if every tree of the island were to be changed into a fighting Iroquois, I am bound to go thither and I will." His fortitude inspired his followers with the necessary courage to withstand the enormous difficulties and still more to face an unceasing danger. A small band far from any possible help, they were practically in the jaws of death, continually exposed to the cruel attacks of the ever menacing Indians.

For years, the colonists had to till their soil with one hand on the plow and the other carrying a musket. The losses were so great that, after ten years,

Bonsecours Market is located in one of the oldest sections of the city. It is opposite the City Hall and next to the Chateau de Ramezay, located near the harbor. On Tuesdays and Fridays, which are market days, the French-Canadian habitant brings his vegetables into Montreal to sell openly on this market. Visitors to Montreal find it a most interesting place to visit.

Old fort at Chambly, on the Richelieu River, 14 miles from Montreal. Built in 1710 on the site of an earlier fort, it has been fought for, taken and re-taken many times, being held in turn by French, British, United States and Canadian forces.

notwithstanding two or three arrivals of recruits, the white population of the island was still but 60. Another decade, and the infant colony very nearly came to its end when seven hundred Iroquois descended the Ottawa River determined on the complete and definitive massacre of the "pale faces." It was saved only by the heroic and almost superhuman sacrifice of Dollard des Ormeaux and his 17 companions, who went to meet the enemy at the Long-Sault and so bewildered them by a fight of several days that the survivors fled back to their country.

Even after the coming, in 1665, of the Carignan Regiment, which was ordered to New France in order to quell the Iroquois incursions, Montreal enjoyed only a relative peace. For years it bore the brunt of the attacks which

occurred and remained literally the bulwark of the country. It was not until the end of the 17th century, after the massacre of Lachine, the last great disaster of the kind, that tranquillity was at last obtained and the city, with a population of about 1,000, began to prosper. Quebec, the capital, was still the chief town, but Montreal was slowly and surely gaining. On account of its privileged situation at the head of inland navigation, it had soon become the recognized center of the fur trade. Indians flocked from all sides to its shores with skins, and at the annual fair especially, the town was the scene of an extraordinary, but somewhat boisterous, activity. Montreal also provided the larger part of the famous "coureurs des bois," who ought to be pardoned for much of their lawlessness in view of the

enormous service they rendered civilization by their adventurous discoveries. Many of the great explorers who paved the way for the development of this continent have hailed from Montreal, LaSalle, Iberville, Lamothe Cadillac, Tonty, Dulhut, Bienville et Perrot.

Thus Montreal continued to thrive as a center of trade and enterprise until the end of the French regime. Its progress was for some time halted by a disastrous fire and still more by a considerable exodus which in a few years reduced the population from 8,300 to 5,700, but it soon resumed its former pace and even increased it. The incoming of the British element, which added to the wonderful qualities of endurance of the sturdy native race its own qualities of resourcefulness and enterprise, gave a new impetus to the life of the community, and at the end of the 18th century, Montreal had already taken the lead over the older city of Quebec, in population as well as in importance. Once more it had been in the throes of the war, in 1775, when, after a first abortive attempt by Ethan Allen, Montgomery finally entered it and raised over its walls the flag of the Independent Colonies. The ordeal, however, was of a short duration and in May, 1776; the city was restored to British rule, never to be disturbed again by invaders. Benjamin Franklin, who came to Montreal as an envoy of the Congress with Chase and Carroll, was not over happy in his mission, but he is none the less thankfully remembered for that most beneficent gift he left them, the printing press.

From that time, the history of Montreal may be summed up in these two

words: progress and industry. Even the political wrangles which were rife in its midst for so long a period, even the War of 1812, which happily left it unruffled—thanks to the timely victory of Salaberry at Chateauguay—even the troublous times of 1837–1838 which so tragically ended with the death on the scaffold of nearly a score of patriots, could not impede its steady march toward greatness.

Everyone remembers the ringing words of Father Vimont, regarding the new settlement of Ville-Marie, as he stood by the side of Maisonneuve, that morning of May 18, 1842, when the little band of religious enthusiasts landed at the spot now occupied by the Customs House: "You are a grain of mustard seed that shall rise and grow till its branches overshadow the earth." There is no question today that the prophecy of the good Jesuit has been amply fulfilled. Montreal is today one of the outstanding cities, not only on this continent, but in the entire world. Covered by two great races as by two powerful streams which, like the Arctusa and the Adriatic sea of old, may not mingle their waters, but none the less flow together and peaceably toward the same ocean of progress, Montreal, with its population of over a million, possesses that peculiarity of being at the same time the second largest city in the British Empire and the second largest French city in the world. It already attracts universal attention by its ever increasing commercial power and by its constantly renewed spirit of enterprise. In the light of its past achievement, it is impossible to foretell where it will stop and we can only watch it grow.

ASSOCIATION NEWS

WESTERN BRANCH A. P. H. A.

THE Second Annual Meeting of the Western Branch, American Public Health Association, was held at Seattle from May 28 to 30. The meeting was called to order by President Hassler at 10 o'clock on the morning of May 28 at the Hotel Olympic. Dr. Hassler delivered a masterly annual address, discussing with vigor a number of particularly live questions of public health interest.

The scientific meetings continued throughout the three days. Papers were of an exceptionally high grade and the program admirably balanced. Appreciation of the excellence of the material presented was shown by the fact that all sessions were fully attended and the audience remained to the end of the meetings, with very little of the usual interruption caused by individuals coming and going during the reading of papers.

The arrangements made by the En-

tertainment Committee, headed by Mrs. C. B. W. Raymond with Mrs. J. W. Hyneman as Vice-Chairman, had made provision for delightful sight-seeing and social events which added much to the complete success of the meeting.

Every credit is due Dr. William P. Shepard, Secretary of the Western Branch, for the completeness of the arrangements made by him in planning the meeting.

Dr. E. T. Hanley, Health Commissioner of Seattle, Wash., was elected President of the Western Branch for the coming year; the three Vice-Presidents elected are Dr. A. L. Beaghler of Denver, Colo., Dr. H. W. Hill of Vancouver, B. C., and Dr. Walter Brown of Stanford University, Calif.; Dr. William P. Shepard of San Francisco, Calif., was reelected Secretary, with W. F. Higby of San Francisco as Treasurer.

The Annual Meeting next year will be held in Denver, Colo.

THINGS OF INTEREST ABOUT THE 60TH ANNUAL MEETING CITY—MONTREAL

In 1535 Jacques-Cartier, sailing up the mighty St. Lawrence, came upon a large fortified Indian village. This Indian village marks the site of a part of present-day Montreal.

Champlain in 1611 established in Montreal a trading post, and in 1642 Paul de Chomedey, Sieur de Maisonneuve, founded the city proper.

Montreal remained under French rule until 1763, when Canada became an English possession under the treaty of Paris.

Montreal has over 250 public schools, which are bilingual, i.e., teaching both French and English languages from the earliest grades.

About 75 per cent of the inhabitants of Montreal are of French origin, which with English, Canadian and American or other nationalities makes it so cosmopolitan in character and so interesting to tourists.

Mount Royal Park in the center of the city has beautiful drives along typical mountain roads to the summit, and

is about 600 feet from the sea level, consisting of approximately 550 acres. Automobiles are not permitted. From the summit a magnificent view is to be had of the city, the harbor and River St. Lawrence, and a distant outline of the Adirondack Mountains.

Montreal, the most important city in Canada, is a thousand miles from the sea, one of the greatest inland ports in the world, and is the national seaport of Canada.

At Montreal terminates the great canal system which brings the water traffic from the West as far as from the head of Lake Superior.

Montreal is the terminus and headquarters of the Canadian Pacific and Canadian National Railways, two of the largest railroads in the world (which are both Transcontinental Lines).

CUSTOMS REGULATIONS

1. The law requires that every person entering the United States shall make a declaration and entry of personal baggage. The senior member of a family present as passenger may, however, declare for the entire family.

(a) Returning residents of the United States must declare all articles acquired abroad, in their baggage or on their persons, whether by purchase, by gift, or otherwise, and whether dutiable or free of duty. Exemption, however, will be allowed by customs officers of articles aggregating not over \$100 in value, if suitable for personal or household use, or as souvenirs or curios, and whether intended for the personal use of the passengers or as gifts or presents to others, provided the articles are not bought on commission for another person nor intended for sale. Articles so exempt from duties must, nevertheless, be declared.

(d) Passengers must not deduct \$100 exemption in making out their declaration. Such deductions will be made by Customs Officers.

Each passenger over 18 years of age may bring in free of duty 50 cigars or 300 cigarettes, or smoking tobacco not exceeding three pounds if for the bona fide use of such passenger. These articles must be declared, but will be passed free by Customs Officers in addition to the \$100 exemption.

(b) The offering of gratuities or bribes to Customs Officers is a violation of law.

6. All articles acquired abroad should be packed, whenever possible, in one receptacle. This will save trouble and inconvenience at time of examination.

(b) United States Customs Officers are located at Windsor and Bonaventure stations. Baggage not examined at these points will be forwarded to destination, if such is a bond port, for examination. If destination is not a bond port, inspection will be made at the frontier.

MEXICAN ANNOUNCEMENT OF A. P. H. A. MEETING

In an editorial in the March issue of *Ingenieria (Publicacion Mensual Organo de la Facultad Nacional de Ingenieros, Mexico)*, the value of meetings such as that of the A. P. H. A. in Montreal is stressed. In particular attention is called to the value of coöperation between the physician and engineer:

The doctor studies, with the aid of his knowledge of diseases, the physiological effects of the many factors which exist in a modern city. He then gives his decision and the remedy. . . . It is not in his power to prevent the cause when it is due to the physical medium in which we live. The engineer completes the task of the doctor. . . . With the aid of his knowledge he designs well conditioned and safe projects in accord with the recommendations afforded by medical science and thus destroys the root of such evil conditions. . . .

Medicine and engineering are the two professions which extend the protecting wings over disease stricken humanity. Their mutual help, their open coöperation, will give us a means for effective welfare. . . .

The American Public Health Association contributes to the realization of this end. It works in order to obtain the scientific ideals which guarantee healthful living conditions. We are proud to place on the first page of this issue the announcement of its future meeting and send our cordial greetings for the success which we are sure it will obtain.

APPLICANTS FOR FELLOWSHIP

LABORATORY SECTION: John W. M. Bunker, Ph.D., Cambridge, Mass.; Lawrence T. Clark, Detroit, Mich.; Henry G. Dunham, Detroit, Mich.; Leon C. Havens, M.D., Montgomery, Ala.; Theodore W. Kemmerer, M.D., Jackson, Miss.; Pearl Kendrick, Grand Rapids, Mich.

PUBLIC HEALTH ENGINEERING SECTION: Aime Cousineau, C.E., Montreal, Que.; Warren J. Scott, Hartford, Conn.; Ellis S. Tisdale, Charleston, W. Va.

PUBLIC HEALTH EDUCATION SECTION: William H. Eaton, M.D., Santa Barbara, Calif.; Clair Van N. Langton, D.P.H., Corvallis, Ore.; Jessie I. Lummis, Denver, Colo.; Richard G. Soutar, Jr., M.D., Sacramento, Calif.

PUBLIC HEALTH NURSING SECTION: Mary A. Brownell, R.N., New York, N. Y.; Mary C. Dickerman, R.N., New York, N. Y.; Anna Heisler, R.N., St. Louis, Mo.; Bertha O. Yenicek, R.N., St. Louis, Mo.

UNAFFILIATED: Harry E. Foster, M.D., Berkeley, Calif.; Wilfred H. Kellogg, M.D., Berkeley, Calif.; Ida M. Stevens, Berkeley, Calif.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A. P. H. A. by the Sub-committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

Gregoire F. Amyot, M.D., D.P.H., N. Vancouver, B. C., Director of Health Unit
Margaret M. Bullard, M.D., King City, Calif., Deputy County Health Officer
Wheeler Davis, M.D., Kennett, Mo., County Health Officer
R. M. Fortier, M.D., Salinas, Calif., Health Officer, Monterey County
William G. C. Hill, M.D., Moundsville, W. Va., Marshall County Health Director
Gustave Lacasse, Tecumseh, Ont., President, Ontario Medical Health Officers Assn.
Francis M. A. McNaughton, M.D., Westmount, P. Que., Health Officer
Roscoe L. Mitchell, M.D., Lewiston, Me., District Health Officer
R. L. Wright, M.D., Poteau, Okla., County Supt. of Health

Laboratory Section

Eudore Giguere, B.A.Sc., Montreal, P. Que., Chief Chemist, Dept. of Health
Louis-Philippe Lebeau, M.D., Montreal, P. Que., Bacteriologist, Provincial Bur. of Health

Vital Statistics Section

Reuben Kaznelson, Ph.D., B.S., Jerusalem, Palestine, Asst. Director, Hadassah General Organization (Assoc.)

Public Health Engineering Section

Herbert M. Bosch, B.S., Jefferson City, Mo., Asst. Public Health Engineer, State Board of Health
Jorge V. Davila, B.S., M.S., Santurce, P. R., Engineer charge of water and sewage purification, Dept. of Health
E. X. Jones, New York, N. Y. (Assoc.)
John L. Oberly, B.S., Chicago, Ill., Ventilation Engineer in charge, City Health Dept.
Frank W. Stock, Stamford, Conn., Nustone Products Corp.

Industrial Hygiene Section

John W. Dugger, M.D., Jackson, Miss., Director, Bur. of Industrial Hygiene
Austin D. Reiley, New York, N. Y., Supervisor of Risks, Mutual Life Ins. Co.

Food, Drugs & Nutrition Section

Jean V. Knapp, D.V.M., Tallahassee, Fla., State Veterinarian
Lillias D. Lund, B.S., Fort Wingate, New Mex., Teacher of Home Economics, U. S. Dept. of Interior, Office of Indian Affairs

Public Health Education Section

Joseph A. Baudouin, M.D., Montreal, P. Que., Professor of Hygiene and Public Health, Univ. of Montreal

Mary E. Elliott, Cambridge, Mass., temporarily student at Simmons College, connected with Walla Walla Health Center
 Abraham J. Levy, Ph.D., M.D., New Haven, Conn., Fellow of Hadassah (Assoc.)
 Louise E. Northup, B.S., Harrisburg, Pa., Director, Health Education Service, Penn Milk Products Co.

Public Health Nursing Section

Lillian Goodall, Ann Arbor, Mich., Student (Assoc.)
 Edna J. Keller, R.N., Dyersburg, Tenn., Dyer County Health Nurse
 Edith Ross, R.N., Van Buren, Mo., Chief Nurse, District Health Dept.
 Mrs. Bertha Stevens, R.N., Springfield, Mo., County Public Health Nurse

Olive M. Whitlock, R.N., Rockport, Mo., County Public Health Nurse
 Dorothy I. Willis, R.N., Boonville, Mo., County Public Health Nurse

Epidemiology Section

Benjamin G. Horning, W. Hartford, Conn., Epidemiologist
 Horace G. MacKerrow, M.D., Worcester, Mass., Tuberculosis Sanitarium
 Elzear Pelletier, M.D., Montreal, P. Que., Consulting Hygienist, Provincial Bur. of Health

Unaffiliated

John W. Armstrong, M.D., Berea, Ky., College Physician, Berea College

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Kansas City's Health—The Chamber of Commerce of Kansas City has sponsored a survey of the health and hospital situation, the study being reported in 3 major divisions: (1) the public health services of the voluntary and tax supported agencies, (2) community aspects of hospital facilities, (3) the administration of the city hospital group.

The application of the *Appraisal Form* of the American Public Health Association indicates that the health services are somewhat less than 70 per cent of the standard. This deficiency is ascribed to the lack of stability and leadership existing in the official health department in the past. There is need of the establishment of a nonpartisan health department. There is now being expended \$1.39 per capita from official and unofficial sources. The leadership in Kansas City has come from the voluntary groups working so far as possible with the official agencies concerned.

There are three groups providing public health nursing service in Kansas City. The Health Department has but 5 nurses while the Board of Education employs 52, and the Visiting Nurse Association 55. Many of the functions of the latter are unquestioned responsibilities of the Health Department, such as the tuberculosis and child welfare services. Complete generalization of nursing service is recommended for consideration in order to secure economy of operation.

Less than one-half of the milk supply is safeguarded by pasteurization. Health education has been carried on

by the Health Conservation Association through affiliated and coöperative agencies and the Children's Bureau.—Health and Hospital Survey of Kansas City, Mo., Kansas City Chamber of Commerce, 1931.

County Health Program—There are at least four factors to be considered in a well balanced rural health program: first, the local problems should be well defined; second, available resources must be made to fit in with local problems; third, the *Appraisal Form* should be used to assist in distributing local effort to meet the various needs of a well rounded health program; fourth, a planned work program will aid in carrying out the proposed program.—F. L. Roberts, *Pub. Health Rep.*, 46, 1079 (May 8), 1931.

Tuberculosis Control in New York State—There were reported in upstate New York in 1930, 7,904 new cases of tuberculosis and 3,844 deaths from this disease. Of 7,216 pulmonary cases reported, 20 per cent were in the minimal stage, 25 per cent moderately advanced, and 33 per cent advanced. There is need of a greater appreciation of the value of diagnostic laboratory service as indicated by the fact that 57 per cent of the cases contained no information regarding examination of sputum.

The State Health Department maintains an itinerant chest clinic at which 5,588 patients were examined, 63 per cent of whom were new cases. Fifty thousand patients were examined during the year at 63 local clinics.—*Health*

News, New York State Dept. of Health, 8, 78 (May 18), 1931.

Whooping Cough in Maryland—During the period 1921–1929 inclusive, there were reported in Maryland 34,238 cases and 1,484 deaths from whooping cough. Baltimore reported 25,062 of these cases. Case reporting is less complete in the rural sections where 56 per cent of the deaths occurred and only 27 per cent of the cases was reported. The loss of time due to illness from whooping cough is not generally appreciated. As the Maryland quarantine period is 30 days, during the period of the study there were 1,027,140 sick days or an average of 3,804 months lost during each year. There has been a slight downward trend in the death rate from whooping cough. The mean rate for

the period 1906–1914 was 16.4 per 100,000 population, while the mean rate for the last 9 years was 10.7.—John Collinson, Whooping Cough in Maryland, *Bull.*, Maryland State Dept. of Health, 1931.

Cleveland Census Tracts—A book has been prepared to present basic population data for Cleveland and to carry a street index which makes possible a geographical distribution of all sorts of statistical units. Such a volume is of great help to all who need population facts, especially dealing with problems of public and private health and for the improvement of social and living conditions.—Howard W. Green, *Population by Census Tracts, Cleveland and Vicinity*, Cleveland Health Council, 1931.

LABORATORY

JOHN F. NORTON, PH. D.

PROPOSED CHANGES IN STANDARD METHODS OF WATER ANALYSIS

AT the meeting of the Committee on Standard Methods of the Laboratory Section of the American Public Health Association at Fort Worth, October 29, 1930, certain changes in methods were recommended in addition to those previously recommended and published in the *Journal* for January, 1930. These changes were approved by the referees involved, and are presented here in order that the members of the Association may have full information and opportunity to comment if they so desire. This report contains the complete description of proposed Standard Methods for the determination of turbidity of

soap hardness to replace those in use at present; a summary of methods for the rapid analysis of water to be used for boiler purposes, these methods being new material as far as "Standard Methods" is concerned but representing what is believed to be the best current practice; and a proposed bacterial method using brilliant green lactose bile medium. Other less important and to a large extent editorial changes will be indicated.

Atomic weights have been brought up to date and necessary corrections made in chemical factors.

The following method is recommended

for the measurement of turbidity: The removal of suspended matter by centrifugating before determination of color is recommended for turbid waters.

The turbidity of water is due to suspended matter, such as clay, silt, finely divided organic matter, microscopic organisms, and similar material.

I. TURBIDITY MEASUREMENTS

Turbidity measurements are based on the depth of solution required for the image of the flame of a standard candle to disappear when observed through the solution. The standard instrument for making such measurements shall be the Jackson candle turbidimeter, which consists of a graduated glass tube, a standard candle, and a support for the candle and tube. The glass tube and the candle shall be supported in a vertical position so that the center line of the tube passes through the center line of the candle, the top of the support for the candle being 7.6 cm. (3 inches) below the bottom of the tube. The glass tube shall be graduated, preferably to read direct in turbidities, and shall have a flat polished bottom. Most of the tube should be enclosed in a metal or other suitable case when observations are being made. The candle support shall have a spring or other device so as to keep the top of the candle pressed against the top of the support. The candle shall be made of beeswax and spermaceti gauged to burn within the limits of 114 to 126 gr. per hour.

To insure uniform results it is desirable that the flame be kept as near constant size and a constant distance below the glass tube as is possible. This will require frequent trimming of the charred portion of the candle string and frequent observations to see that the candle is pushed to the top of its support. Each time before lighting the candle remove such portion of the charred part of the string as is very easily broken off with the fingers. Do not keep the candle lighted for more than a few minutes at a time, for the flame has a tendency to increase in size.

The observation is made by pouring the solution into the glass tube until the image of the candle flame just disappears from view. Pour slowly when the candle becomes only faintly visible. After the image has disappeared the removal of 1 per cent of the solution from the tube should make it again visible. Care should be taken to keep the glass tube clean on both the inside and the outside. The accumulation of soot or moisture on the lower side of the glass bottom of the tube may interfere with the accuracy of the results.

The figures in Table I give the turbidities for the depth at which the image of the candle just disappears.

TABLE I

GRADUATION OF CANDLE TURBIDIMETER				
Depth of Liquid (cm.)	Turbidity	Depth of Liquid (cm.)	Turbidity	
2.3	1,000	10.3	200	
2.6	900	10.8	210	
2.9	800			
3.2	700	11.4	190	
3.5	650	12.0	180	
		12.7	170	
3.8	600	13.5	160

Observations should be made in a darkened room or with a black cloth over the head. It is allowable to substitute for the standard candle other forms of light, but the instrument must be calibrated to give turbidity readings that correspond with the standard candle.

II. TURBIDITY MEASUREMENTS BELOW 25

It is evident that the candle turbidimeter cannot be used for the direct measurement of low turbidities. When the turbidity is below 25 it is better to make the determinations by comparing with standards of known turbidity. For turbidities between 5 and 25, approximate results may be obtained by comparing in bottles with standards of known turbidity. Below 5, it is better to use some kind of an

instrument especially designed for low turbidity comparisons such as the Baylis turbidimeter.¹

Preparation of Standards—Add 2 or 3 gm. of fuller's earth to about 1 liter of distilled water, thoroughly agitate several times within a period of 1 hour, and then allow to stand about 24 hours. Withdraw part of the supernatant liquid without disturbing the sediment on the bottom, and test the turbidity with the Jackson candle turbidimeter. If the turbidity is less than 25, add more earth, allow to stand an additional 24 hours, and repeat the testing until a turbidity of at least 25 is obtained. It is better to use an amount of the earth that will give a turbidity less than 50. This constitutes the stock solution, which will remain in fairly good condition for several months. Before using the stock solution for making turbidity standards thoroughly agitate and make a turbidity measurement with the candle turbidimeter. The turbidity may change slightly on standing.

Dilute portions of the stock solution to the desired standards with zero-turbidity distilled water. For turbidity readings between 5 and 25, standards of 5, 10, 15, 20, and 25 may be prepared. Turbidities between zero and 2.0 may be measured by comparing the standards in the Baylis turbidimeter. To cover this range, standards of 0.1, 0.2, 0.4, 0.6, 0.8, 1.0, 1.2, 1.4, 1.6, 1.8, and 2.0 should be prepared. The quantity of stock solution required to prepare a certain standard is the volume of the standard multiplied by the desired turbidity and this divided by the turbidity of the stock solution. If the stock solution has a turbidity of 30 and it is desired to prepare 500 c.c. of 0.6 turbidity, (500×0.6) divided by 30 gives 10 c.c. of the stock solution.

Procedure—When the turbidity is between 5 and 25 approximate determinations may be made by comparing the samples in bottles with standards of known turbidity. This should be done in clear glass bottles, preferably of 1 liter capacity or greater. The comparison shall be made by viewing both sample and standard sidewise, looking at some object and noting the distinctness with which the margins of the object can be seen. The standards shall be kept stoppered, and both standard and sample shall be thoroughly shaken before making the comparison. The standards should be made fresh at least every month. In order to prevent any bacterial or algal growths from developing a small amount of mercuric chloride may be added to the standards.

For making turbidity measurements between 0.0 and 2.0 with the Baylis turbidimeter, fill

one of the long glass tubes with the water to be tested. Allow to stand until all air bubbles rise to the surface, which is usually between 5 and 10 minutes. Observe the sample before filling the other tube with a standard of known turbidity and make a guess at the turbidity. Use the standard nearest the guess, and when the air bubbles have disappeared from the standard, which is usually between 1 and 2 minutes, make a comparison. If the sample varies from the standard, use another standard and continue until the one nearest that of the sample is found. Standards standing in the glass tube more than 2 or 3 hours should be thoroughly agitated before making a comparison. Keep the glass tubes filled with water above the line where the light strikes the tube; otherwise corrosion of the glass at the water line may interfere with the results. The glass tubes should be kept clean on both the inside and outside. Do not handle the tubes below the line where the light strikes them.

Turbidities between 2.0 and 5.0 shall be made by diluting the sample with zero-turbidity distilled water to a turbidity less than 2.0 and comparing in the Baylis turbidimeter, or the test shall be made by the use of some instrument designed for turbidity comparisons that will give accurate results.

Turbidities between 5 and 25 also may be diluted below 2.0 for comparison in the Baylis turbidimeter, unless a more accurate method than comparison in bottles is available. Direct observation in color comparison tubes gives fairly good results when the color is less than 10.

The results of turbidity observations shall be expressed in numbers which correspond to units of turbidity as follows:

Turbidities	0.0 and	5.0 recorded	to the nearest	tenth
"	5	50	"	unit
"	51	100	"	5
"	101	500	"	10
"	501	1,000	"	50
"	1,001	greater	"	100

III. COEFFICIENT OF FINENESS²

The quotient obtained by dividing the weight of suspended matter in the sample by the turbidity, both expressed in the same units, shall be called the coefficient of fineness. The samples shall be filtered through a fine

alundum crucible or some suitable filter that will remove all the suspended matter. The crucible shall then be dried to constant weight in an oven at 110° C.

For waters high in organic matter, a temperature of 103° C. is recommended for the drying of solids.

The following method is recommended for the determination of hardness by the use of standard soap solution.

REAGENTS

1. *Standard Calcium Chloride Solution*—Dissolve 0.5 gm. of pure calcite (calcium carbonate) with a little dilute hydrochloric acid, being careful to avoid spattering. Wash down with carbon dioxide free distilled water and neutralize with ammonium hydroxide to slight alkalinity, using litmus as an indicator. Make up to 500 c.c. with carbon dioxide free distilled water and store in glass stoppered bottle. One c.c. of this solution is equivalent to 1 mg. calcium carbonate.

2. *Standard Soap Solution*—Make up stock solution by shaking vigorously approximately 100 gm. of pure powdered castile soap in 1 liter of 80 per cent grain alcohol. Let this solution stand at least over night and decant. Titrate against the CaCl_2 solution and dilute with 70 per cent grain alcohol until 1 c.c. of the resulting solution is equivalent to 1 c.c. of the standard calcium chloride solution, making due and recorded allowance for a lather factor from at least five determinations. The lather factor will vary from 0.5 to 1.4 c.c. with different soaps. Carbon dioxide free water should be used for lather factor determinations and standardization of the solution. One c.c. of this solution after subtracting the lather factor is equivalent to 1 mg. calcium carbonate.

3. N/50 sulphuric acid
4. N/50 sodium carbonate
5. Phenolphthalein indicator
6. Methyl orange indicator

ANALYTICAL PROCEDURE

1. *Hardness*—Measure 50 c.c. of the water to be examined into an 8-oz. bottle. Add the standard soap solution in small amounts at a time, shaking vigorously after each addition, until a strong permanent lather is secured which will stand for 5 minutes. It is usually satisfactory to add an amount of soap solution equal to the lather factor as the first addition and then, as the end point is approached, to cut the additions of soap solution to 0.1 c.c. or more, depending upon the

accuracy desired and the experience of the manipulator. Note and record any false end point which is the dividing line between the calcium and magnesium salts. The final burette reading, after deducting the lather factor, gives the total hardness ("H") in terms of calcium carbonate as p.p.m. when multiplied by 20. (In determining the hardness of acid waters they should first be rendered neutral to methyl orange by addition of N/50 sodium carbonate solution. Samples containing appreciable amounts of free carbon dioxide should be neutralized to faint pink with N/50 normal sodium carbonate solution before testing.) The difference between the false end point and the total hardness indicates the amount of magnesium salts, the balance being calcium salts, all, when multiplied by 20, expressed as p.p.m. in terms of calcium carbonate. If the hardness test requires more than 7.5 c.c. of soap solution, it is best to take an aliquot portion and dilute to 50 c.c. with carbon dioxide free distilled water so that the final lather point will be less than 7.5 c.c. After deduction of the lather factor, multiply the result accordingly to obtain correct hardness value.

(NOTE: If it is desired to express results in terms of gr. per gal. use a 58.3 c.c. sample of water and the results can be read direct as gr. per gal. in terms of calcium carbonate after subtracting the lather factor.)

For field work, the following solution and method is recommended.

Dissolve 100 gm. of pure soap in 1,600 c.c. of 90 per cent grain alcohol. Dilute with distilled water (800 to 1,000 c.c. will be required) until 2.4 c.c. of the soap solution gives a lather with 40 c.c. of a solution of CaCl_2 containing 0.25 gm. per liter. The CaCl_2 solution may be made up by dissolving the proper amount of pure CaCO_3 , using the technic described above (see standard soap).

This soap solution is approximately $3\frac{1}{2}$ times as strong as the standard soap previously described and is to be used for field determinations of "zero hardness." For this purpose 40 c.c. of the water to be tested are placed in a 3-oz. cork stoppered bottle and the soap solution added a drop at a time from any convenient type of dropping bottle which delivers 0.05 c.c. per drop. The sample is shaken vigorously after each addition of soap. Three drops should give a permanent lather with 40 c.c. of distilled water or water of "zero hardness."

Directions for titration with erythrosine have been modified.

The drop ratio method for the determination of hydrogen ion concentration has been omitted. It is recommended that the results of mineral analysis be expressed in p.p.m. and milli-equivalents.

The following colorimetric method for the determination of silica is suggested.

REAGENTS

1. Ammonium molybdate reagent:
30 gm. of ammonium molybdate
200 c.c. of 1:1 HCl
400 c.c. of water
2. Standards:
0.530 K_2CrO_4 in 100 c.c. water
1 c.c. of this solution is equivalent to 1 mg. SiO_2 .
Permanent standards reading directly in p.p.m. when a 50 c.c. sample is used may be made as follows:

c.c. of chromate diluted to 55 c.c.	Equivalence in p p m. SiO_2 when 50 c.c. sample used
0.0	0
0.1	2
0.2	4
0.3	6
0.4	8
0.5	10
0.6	12
0.7	14
0.8	16
0.9	18
1.0	20
1.1	22
1.2	24
1.3	26
1.4	28
1.5	30

Procedure—Fifty c.c. of the sample are measured into a tall form Nessler tube. Five c.c. of the molybdate reagent are added. The mixture is thoroughly shaken and allowed to stand about 15 minutes—not longer than 20 minutes. The yellow color developed is then compared with the chromate standards.

The limitations of this method are:

1. It will not determine suspended silica.
2. Phosphates interfere.
3. Strong mineral acids in excess of that present in the reagent will prevent the development of maximum color.
4. Hydrogen sulphide gives a blue color instead of yellow and must therefore be removed.

This method was suggested by L. W. Winkler¹ and modified in the Illinois State Water Survey laboratory by S. L. Neave.²

Slight modifications have been suggested in the descriptions for the determination of total and suspended solids and of grease.

A report has been prepared by R. C. Bardwell recommending Rapid Methods for the Analysis of Boiler Waters. These methods include both those for field and for laboratory work. They are not given here in full because they represent well recognized procedures. However, a copy giving the complete details can be obtained from the Secretary of the Committee.

A brief summary of these methods is as follows: It is recommended that combinations of positive radicals should be made with negative radicals in the following order when it is desired to report the results in hypothetical combinations.

Positive Radicals	Negative Radicals
Calcium	Carbonate
Magnesium	Sulphate
Potassium	Chloride
Sodium	Nitrate

Total hardness is determined by means of soap solutions. Alkalinity and acidity are determined by titration with N/50 sulphuric acid and N/50 sodium carbonate respectively, using methyl orange as an indicator. Non-carbonate hardness is determined by means of soda reagent and a volumetric procedure of magnesium is given.

The following method for the determination of *B. coli* by means of brilliant green lactose peptone bile medium is recommended with the proviso that it be used only for water purification plant control.

BRILLIANT GREEN LACTOSE PEPTONE BILE

This medium may be used for parallel planting with standard lactose broth, for water purification plant control, only. It contains brilliant green in a concentration of 1:75,000 and 2 per cent of bile.

REFERENCES

1. *Ztschr. f. anal. Chem.*, 54: 365, 1914.
2. Not published.

Dissolve 10 gm. of peptone and 10 gm. of lactose in 500 ml. of distilled water. Add 200 ml. of fresh ox bile (or 20 gm. of dehydrated bile) and 13.3 ml. of a 0.1 per cent solution of brilliant green (certified dye) in water. Make up to a volume of 1,000 ml. with distilled water, adjust the reaction to a pH of 7.1-7.4 and filter through cotton. Distribute in tubes with inverted vials and sterilize as directed under sterilization. The reaction after sterilization should be 7.1-7.4.

When 10 ml. or more of water are to be planted, the concentration of ingredients should be increased as indicated in the following table:

Amount of Water Sample	Concentration of Ingredients per 1,000 ml. of medium	Amount of medium per tube
1 ml. or less	peptone, 10 gm. lactose, 10 gm. ox bile, 200 ml. brilliant green, 0.1% solution, 13.3 ml.	10 ml.
10 ml. or 100 ml.	peptone, 20 gm. lactose, 20 gm. ox bile, 400 ml. brilliant green, 0.1% solution, 26.6 ml.	10 ml. or 100 ml.

Amount of Water Sample	Concentration of Ingredients per 1,000 ml. of medium	Amount of medium per tube
10 ml.	peptone, 15 gm. lactose, 15 gm. ox bile, 300 ml. brilliant green, 0.1% solution, 20 ml.	20 ml.
10 ml.	peptone, 13.3 gm. lactose, 13.3 gm. ox bile, 266.6 ml. brilliant green, 0.1% solution, 17.7 ml.	30 ml.

The medium may be used in the dehydrated form in the following concentrations:

Amount of Water Sample	Concentration of Ingredients per 1,000 ml. of medium	Amount of medium per tube
1 ml. or less	40 gm.	10 ml.
10 ml. or 100 ml.	80 gm.	10 ml. or 100 ml.
10 ml.	60 gm.	20 ml.
10 ml.	53 gm.	30 ml.

(To be continued)

PRESERVATION OF HEMOLYTIC AMBOCEPTOR

M. P. MOON

*Department of Medical Bacteriology and Preventive Medicine,
University of Missouri School of Medicine, Columbia, Mo.*

THE usual method of the preservation of hemolytic amboceptor is by addition of 50 per cent of sterile neutral glycerin. Phenol 0.4 per cent, and tricresol 0.3 per cent have also been used. It is common experience that the titer of such preserved amboceptor slowly decreases, and it is customary to retest it about every 3 months.

The use of mercuric chloride as a desirable preservative, advocated by Daranyi, warrants consideration. Daranyi prepared a "stock solution of corrosive sublimate; 1.0 gm. of mercuric chloride is dissolved in 250 c.c. of physiological salt solution. Of this solution, 1/20 part by volume is to be

mixed quickly with the serum. The corrosive sublimate is present in the serum in a final dilution of 1:5,000

TABLE I
COMPARISON OF TITER OF HEMOLYTIC AMBOCEPTOR ACCORDING TO KIND OF PRESERVATIVE

Hemolytic Amboceptor	Pre-servative	Titer			Ap-pearance
		Mar. 1929	May. 1930	May. 1931	
	Glycerin	1:2,000	1:1,200	1:600	Slight cloudiness
	Hg-Cl ₂ 0.02%	1:2,000	1:1,700	1:800	Clear

(0.02 per cent)." In serum preserved by the mercuric chloride method, Daranyi found after a half year no diminution of titer.

I divided a fresh supply of hemolytic amboceptor, attenuated, into two portions, according to Table I.

In this particular experiment, the titer of the corrosive sublimated amboceptor decreased more slowly than the glycerinated amboceptor, especially during the

first year. HgCl_2 appears to be a desirable preservative for hemolytic amboceptor.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Vital Statistics for Kentucky, 1930—For the state of Kentucky the general death rate in 1930, of 11.3 per 1,000 population, is 0.8 lower than in 1929. There were 1,324 fewer deaths than in the previous year. The causes from which the number of deaths increased in 1930 were meningitis, measles, typhoid fever, infantile diarrhea, diarrhea in adults, infantile paralysis, malaria and cancer. With the probable exception of meningitis the increased rate from the other causes is undoubtedly due to the drought conditions existent in the state. There were 2,468 deaths from tuberculosis, with a rate of 94.4, as against 2,654, with a rate of 103.9 in 1929. This is the first time since enactment of the vital statistics law in 1910 that the tuberculosis rate has fallen below 100.0. Eight hundred deaths were attributed to influenza; 3,239 resulted from this cause in 1929. Cancer deaths increased 213 over the previous year, showing a rate in 1930 of 68.4. The number of births registered increased 283 over 1929, but due to increase in the recorded population, the rate is somewhat lower, being 21.8 as

against 22.2 in 1929. The infant mortality rate of 66.5 is the second lowest ever recorded in the state.—*Bull.*, State Board of Health of Kentucky, 3: 5 (Apr.), 1931.

Vital Statistics for New Jersey, 1930—The lowest general death rate, tuberculosis death rate and infant mortality rate ever attained in New Jersey were reached in 1930. Preliminary rates, subject to slight corrections, show that the state death rate for 1930 was 10.63 per 1,000 estimated population. This was the lowest rate ever attained in New Jersey, the previous low being 11.43 in 1927. The estimated midyear population for 1930 was 4,062,930. The rate from all forms of tuberculosis was 69.0 per 100,000 population, which compared favorably with a rate of 90.1 from the same disease only 7 years ago. The death rate from cancer and other malignant tumors, 106.6, was lower than the 1929 rate of 116.4. The latter was the highest ever recorded in New Jersey. The pneumonias showed a decreased rate. For 1929 the rate was 109.5 per 100,000 population and for 1930, 77.4.

Approximately 68,200 births were reported as occurring in 1930, which was equivalent to a rate of 16.79 per 1,000 inhabitants. The low figure for 1930 was merely a continuance of the decline noted since 1917, when the rate was 24.98. The number of deaths of infants under 1 year of age per 1,000 babies born alive was 56.7, which was the lowest infant mortality rate in New Jersey since such rates were first published in 1906. The approximate number of mothers who died as a result of childbirth was 390, or 5.7 per 1,000 babies born alive. This compared with 5.3 for the preceding year.—*Pub. Health News*, New Jersey State Dept. of Health, 16: 85 (Mar.), 1931.

Marriages in New York State—1930—The marriage rate in the state of New York in 1930 was, with the single exception of 1908, the lowest recorded in the last 30 years. The number of marriages was 108,498 and the marriage rate 17.2 per 1,000 population as compared with 114,644 marriages and a rate of 18.4 in 1929.

It is a well known fact that the marriage rate fluctuates in direct response to important sociological and economic phenomena. The financial panic of 1907 was reflected the following year in a drop in the marriage rate of 22 per cent—the greatest ever recorded in the state. Our entrance into the World War was the primary cause for the low rate in 1918, which was 14 per cent below that of the preceding year. The highest rate for the state (21.6) was recorded in 1920—the marriages in that year including undoubtedly many that were postponed because of war conditions. The second highest rate (21.5) was that of 1907—the third successive year of unusually favorable business conditions preceding the panic in the last quarter of that year and the depression of 1908. The exceptionally low rate of 1930 is a direct consequence

of the widespread economic depression which first manifested itself in the late fall of 1929.

The marriage rate according to age had a low point at the youngest age rising to a maximum at 21 years for both brides and grooms and declining to a minimum in the oldest group. There were 2,838 brides and 2,515 grooms below the ages of consent. In 33 marriages the bride was 14 years of age and in 198 marriages, 15 years of age. There were 11 grooms 16 years of age and 84 grooms 17 years old. Most of these young brides and grooms were native born white; of the 33 brides who were 14 years old, 30 were native born white, 1 a native of Canada, and 2 negroes. Of the 198 brides 15 years of age, 178 were native born white, 5 natives of Canada, 5 of Italy, and 10 negroes. Of the 11 grooms who were 16 years of age all were native born white. Of the 84 grooms who were 17 years of age, 79 were native born white, 2 natives of Canada, and 3 negroes. At the farther end of the life span, there were 15 marriages in which the grooms were over 80 years of age; 14 native born white and 1 a native of Germany; the oldest brides were between 75 and 80 years of age. Of these, 12 were native born white, 1 a native of Germany, and 1 of Poland.—*New York State Weekly Health News*, 8: 65-66 (Apr. 27), 1931.

Tuberculosis in India—Tuberculosis has been a most prevalent disease in most Indian cities from ancient times, but there is evidence that it has rapidly increased within recent years, e.g., there has been an increase of 70 per cent in mortality from tuberculosis within the last 10 years in the city of Calcutta. The course of the disease seems to be more acute than in western countries. To understand the epidemiology of tuberculosis in India, it must be remembered that 90 per cent of India's popu-

lation still reside in the villages, and that urbanization, modern industrialism and the introduction of rapid transit facilities have been powerful factors in the diffusion of population during the last 50 years. Certain habits, such as spitting inside habitations, eating and drinking from common vessels, and sleeping together in the same room, are extremely common among all classes of society and favor massive infection. The malnutrition factor appears noteworthy, for the diet of the people in most parts of India has become unbalanced and inadequate within the same period. Another fact of great importance is that infection with the bovine type of tubercle bacillus is practically nonexistent in India. Only 2 or 3 per cent of cattle slaughtered in the slaughter houses show localized tubercular lesions.

Five years' mortality figures in the city of Calcutta show a very low death rate in the earlier years, reaching only 4 per cent by the 15th year. The curve rises rapidly from this age and attains its highest point at 30 years, falling down rather more slowly and reaching about 7 per cent by the 60th year. The initial peak of mortality which comprises nearly 15 per cent of the total deaths from tuberculosis in England and Wales and in most European countries is thus lacking. The Health Officer's report in Calcutta states that 94 per cent of the deaths are from pulmonary tuberculosis. The extremely low incidence among infants and children below 10 years of age is noteworthy. The incidence, however, rises high in the presence of a constant source of infection, e.g., according to a survey of 100 houses containing "open" pulmonary cases, 71.4 per cent of children between 1 and 5 years, and 83.3 per cent of children between 6 and 10 years were found to give positive reactions when they lived in the same room with such a case. What, however, is puzzling to authorities is the low figure of mor-

talidity at this age in the presence of a low degree of positive cuti-reactions.

In a series of 52,550 cases attending the Polyclinic of the Calcutta hospitals, the following incidence of tuberculous disease was found: Total number of tuberculosis cases, 1,019, of which the lungs were found affected in 62.8 per cent; glands in 17 per cent; bones and joints, 13.9 per cent; while skin tuberculosis accounted for only 2 in the series. Lung tuberculosis was found to be extremely rare below 10 years. All the forms of tuberculosis attained their maximum incidence between 25 and 30 years, 5 to 10 years earlier than those found in Europe. The duration of life of a case of pulmonary tuberculosis, which depends on the infecting dose, the age, the extent and multiplicity of lesions, the secondary bacterial flora in "open" cases and on the immunity of the individual, is distinctly shorter in India than in Europe. Further, it is shorter in females than in males. Pregnancy and lactation, diabetes, influenza, and kala-azar have been found to shorten the course. The lesions seldom remain localized, rapidly spreading to other parts of the lungs. Massive infection is the rule in a majority of cases.—A. C. Ukil, A Note on the Epidemiology and Pathology of Tuberculosis in India, *Tubercle*, 12: 244-250 (Mar.), 1931.

Provisional Mortality Report for Wisconsin, 1930—For the year 1930, Wisconsin, according to provisional reports, showed 30,261 deaths exclusive of stillbirths, this figure bringing the death rate per 1,000 population down to 10.3, as compared with 10.8 in 1929, 11.0 in 1928 and 10.4 in 1927. The death rate from tuberculosis for 1930 will undoubtedly be the lowest rate from this disease ever recorded in the history of the state. With a total of 1,490 deaths reported for 1930, the death rate was only 50.7 per 100,000 as compared

with a rate of 59.0 in 1928 and 55.2 in 1929. In 1929, with the lowest death rate ever recorded for diphtheria in Wisconsin, there were 79 deaths from this disease and in 1930 there were only 72 deaths reported, bringing the death rate down to 2.4 as against 2.7 and 3.5 for 1929 and 1928 respectively. There were no serious outbreaks of influenza in Wisconsin during 1930, and as a result only 470 deaths from influenza were reported as compared with 1,251 in 1929, reducing the high 1929 death rate of 42.1 to 15.9 in 1930. With the marked decline in the number of cases and deaths from influenza there was a considerable decline in the number of deaths from pneumonia, with a death rate of 72.6 in 1930 as against 77.2 in 1929.

There was practically no increase in the number of deaths from cancer during the past 3 years, the death rate for 1930 being 112.5. The reports for 1930 show a slight decline in the death rate from puerperal causes, 4.8 in 1930 as compared with 4.9 in 1929 and 5.8 in 1928. Epidemic meningitis deaths declined to about one-half, reducing the 1929 death rate of 3.9 from this disease to 2.0 in 1930. As contrasted with these declines in death rates, there was a marked increase in the number of suicides from 451 or a rate of 15.5 in 1929 to 546 or a rate of 18.9 in 1930. The death rate from automobile accidents also increased from 24.1 in 1929 to 26.9 in 1930. Measles and smallpox showed increases for 1930.

With 55,784 births reported for 1930 and 3,134 deaths reported among children under 1 year of age, the provisional infant mortality rate based upon the number of deaths among children under 1 year of age per 1,000 live births reported was 56.2. This is the lowest infant mortality rate ever recorded, in Wisconsin, and with the several hundred delayed 1930 birth reports which remain to be put on record, it is believed

that the final figures for infant mortality will be even slightly below 56.2.—*Bd. of Health Bull.*, State of Wisconsin, 5: 21-26 (Jan.-Mar.), 1931.

Suicides in New York State Reach New Maximum in 1930—Suicides in 1930 in the entire State of New York numbered 2,345, the greatest total ever recorded. The suicide rate, 18.6 per 100,000 population, was 22 per cent above the average rate for the preceding 5 years. Compared with 1929 the number of suicides increased in the entire state by 210, in New York City by 148, and in the rest of the state by 62. The increase in suicides in the state occurred mainly among men, the number rising from 1,563 in 1929 to 1,760 in 1930; among women, the increase was but slight—from 574 to 585. In the period 1920-1930 the number of suicides doubled from 1,189 to 2,345 while the population of the state increased by only 21 per cent. Suicides of men rose from 853 to 1,760—an increase of 106 per cent; suicides of women rose from 336 to 585, or 74 per cent.

The proportion of suicides to deaths from all causes in 1930 increased with age from a low point under 20 years to a maximum at 30-39 years, gradually declining to another low figure in the oldest group. In the age group 10-19 years, 12 out of 1,000 deaths were suicides; the ratio was 38 in 1,000 death at 20-29 years, rising to 41 at 30-39 years. The absolute minimum proportion—2 in 1,000 deaths—was recorded in the oldest group, 80 years and over. In New York City the number of suicides in relation to deaths from all causes was greatest between 30 and 40 years—46 in 1,000 deaths; upstate, between 20 and 30 years—35. There were 30 suicides of young persons under 20 years of age in New York City and 18 upstate. All but 1 of the suicides upstate were native born—the youngest, a boy 9 years of age. There were in

New York City 6 suicides of men and 2 of women over 80 years of age; upstate, 22 and 2. Three times as many men as women took their own lives. In the oldest age group, 80 years and over, there were 7 suicides of men to 1 woman. The next highest ratio, 4:1, was between 50 and 70 years. In the youngest ages the disparity was considerably less, suicides among men being only one and one-half times the number among women. Practically two-thirds of the men were between the ages of 30 and 60; the corresponding proportion of suicides among women fell between the ages of 20 and 50.

In about one-third of the suicides, poisonous gas (mainly illuminating gas and carbon monoxide) was the means employed; hanging, in 21 per cent; firearms, 15 per cent; jumping from high places, 10 per cent; and corrosive substances (bichloride of mercury, carbolic acid), 10 per cent. Poisonous gas was the leading means of suicide at all ages to the 70th year; in the older ages, hanging. Next in order of numerical importance were: under 20 years of age, corrosive substances; between 20 and 40

years, firearms; between 40 and 70 years, hanging; after the 70th year, poisonous gas. Among men, the most prevalent methods were: poisonous gas—30 per cent, hanging—24 per cent, firearms—19 per cent; among women, poisonous gas—39 per cent, corrosive substances—17 per cent, jumping from high places—15 per cent. There was considerable divergence in the means of suicide in New York City and in the urban and rural parts of the rest of the state. In New York City: poisonous gas—44 per cent, hanging—15 per cent, jumping from high places—15 per cent; in the urban upstate territory: hanging—26 per cent, firearms—21 per cent, poisonous gas—20 per cent; in rural New York: firearms—30 per cent, hanging—30 per cent, drowning—13 per cent.

There were 29 suicides in state institutions, located outside of New York City; 19 in state hospitals, 7 in state prisons, and 1 each in Craig Colony at Sonyea, Syracuse State School, and the Institution for Defective Delinquents at Napanoch.—*New York State Weekly Health News*, 8: 77-78 (May 18), 1931.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

THE MILK CONTROL PROGRAM IN TEXAS *

FRED B. GREEN, D. V. M.

Milk Supervisor, Texas State Department of Health, Austin, Tex.

IN this discussion it will be my purpose to point briefly to some of the accomplishments of the standard milk ordinance program in Texas rather than to attempt to do full justice to all of the progress that has been made. For public health reasons alone the program was adopted by the State Department of Health in 1924, and its promotion since that time has been to provide cities with a means of producing clean safe milk at the lowest possible cost to the dairyman and the consumer.

In introducing the standard milk program in Texas our health officials realized that they were dealing with one of the world's largest industries, and one that affects vitally the future prosperity of the state as well as the health of her inhabitants. Consequently, they knew that the enactment of any law or the enforcement of any legislation which would hinder the industry would be undesirable. Regulations to govern the production of milk should at the same time encourage its wider use. A workable ordinance was therefore one that was fair, impartial, and economical. It was found that the standard milk ordinance was designed with that in mind.

While the standard milk ordinance is local in its application, the State Department of Health was charged with

coördinating and unifying the program for the state as a whole—a program that was in the course of 5 years to envelope the entire state. With the passage of the ordinance first by a little east Texas town late in 1924, an old industry was reborn. It was there that dairymen demonstrated the principles of milk sanitation as laid down in the standard milk control code, producing a milk superior in quality and one that could be transported, retained, or consumed at leisure. Milk sanitation there made possible the long haul, providing a market for fluid milk which had heretofore been a perishable product. New possibilities in the field of dairy husbandry were opened. Through standardization a definite milk program was established, and the confidence of the milk drinking public was insured.

Today Texas has some 96 towns operating under the standard milk ordinance. Some of these towns have made enviable records in milk sanitation, and others have done little. Failure may be attributed chiefly to lack of funds to carry on the work, politics, and incompetent inspectors. Notwithstanding these disturbing factors, the program has gone far toward promoting a wholesome respect for clean milk production, and its ever growing popularity speaks for its simplicity and efficiency in operation.

The program is not one of big buildings and much money. Fine barns and expensive equipment are not the prime

* Read at a Joint Session of the Public Health Engineering and the Food, Drugs and Nutrition Sections of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

requisites of clean milk production. Such outward camouflaging often cloaks bad methods of operation, and the real fundamentals of milk sanitation may be lost to the inspector in a mass of elaborate construction. Those factors that contribute most to the production of clean milk are simple, and, as outlined by the standard milk ordinance, are within the reach of every dairyman.

The standard milk ordinance is the result of years of study. It is the cream of some 400 nondescript milk ordinances from over a wide geographical area. Of the 25 items listed on the grade sheet not one could be omitted without jeopardizing some phase of clean milk production. A glance at the grade sheet shows the first objective to be dairy herds free of tuberculosis and dairy employees free of communicable disease. No one could dispute the importance of such measures for health protection, especially since bovine tuberculosis contributes 25 per cent of the tuberculosis of the human family. When we add to that the economic losses to the dairy industry due to the ravages of this most dreaded disease, we have some idea of the enormity of the hazard. Texas is fortunate in that it has a relatively small percentage of infected cattle. While other states are spending millions of dollars for the eradication of tuberculosis among cattle, Texas, through the standard milk program and the work of the Livestock Sanitary Commission, has cleaned up thousands of dairy herds, reducing the hazards of tuberculosis without the

alarming influence of state legislation.

Because of the standard milk ordinance thousands of dairy barns have been built—barns that are a source of pride to their owners—which provide shelter for thousands of dairy cattle. The standard ordinance has also built a correspondingly large number of milk houses that are symbols of cleanliness and an inspiration for the dairy industry. Sanitation has been introduced on the farm, many health hazards being reduced or eliminated thereby. The incidence of typhoid fever has been reduced by the construction of proper toilets and the systematic analysis of many water supplies.

Through its frank support of complete pasteurization, the standard ordinance has unconsciously thrown a protective barrier around the production of raw milk. The ordinance has exemplified the importance of regular physical examinations for the dairy attendant, thereby aiding the individual in maintaining good health. The principles of the standard milk ordinance are now being taught in the schools, having been added to the courses in dairy husbandry at Texas A. & M. College, and among other schools of higher learning. New interest has been aroused in the production and distribution of the world's greatest food, and new dignity added to the labor that industry entails. Through the inspection service provided by the standard milk ordinance, the health of our people is being safeguarded and the future of a great industry assured.

DISCUSSION

JAMES STEWART, M. D.

State Health Commissioner, Jefferson, Mo.

THE earliest efforts of the State Board of Health of Missouri toward the improvement of municipal

milk supplies was in 1923. Under the direction of the division of public health engineering, a cooperative pro-

gram with several cities was started, using an ordinance recommended by the State Board of Health. The program was inaugurated for the following reasons:

1. A high infant mortality rate
2. Requests from several unofficial civic organizations, such as commercial clubs, parent-teacher associations, etc., for information regarding the quality of their respective city milk supplies
3. Requests from city officials for assistance and advice relative to certain problems in milk sanitation
4. Information from various sources indicating unsatisfactory or no city milk ordinances in many instances and ineffective enforcement of existing ordinances in practically every city investigated

In brief, the program provided state aid to any city wishing to control milk sanitation. After an ordinance was passed and enforcement well started, the assistance of the State Board of Health ceased.

After 2 years this work was not proving entirely successful for the following reasons:

1. No regular supervision by the State Board of Health
2. Defects in the sanitary features of the ordinance recommended
3. Difficulty in enforcing the ordinance
4. Lack of adequate state personnel

In 1925 the U. S. Public Health Service Standard Milk Ordinance program was adopted, since it offered solution to many previous difficulties, and because of the increasing evidence of the need of safer municipal milk supplies. For the last 2 years this program has received continuous supervision by the State Board of Health and the U. S. Public Health Service. To date the ordinance has been passed in 26 cities in Missouri, representing a total population of 324,500, whose milk supply is produced under standard ordinance requirements. The total population of all cities having

2,500 and over, exclusive of Kansas City and St. Louis, is, according to the 1920 census, 489,596. Thus, 66 per cent of the population of cities of 2,500 and over, exclusive of Kansas City and St. Louis, are living in Standard Milk Ordinance cities. Surveys and some preliminary work toward the inauguration of milk sanitation programs have been undertaken in 20 additional cities with a population of approximately 100,000.

In the majority of cities accepting the Standard Milk Ordinance program it has been necessary to train inspectors who had no previous milk sanitation experience, since this was the best arrangement that could be effected. We are convinced that the success of a milk sanitation program is directly proportionate to the training and ability of the local inspector, backed by adequate support from the city officials. It is certain that far better results have been possible with the untrained personnel, which has been available, through the system of state and federal supervision than could have been obtained without this supervision. Also, it has been shown that trained local enforcement personnel does better work under supervision, possibly due to moral support and aid or because of periodic check-ups.

Our experience in Missouri cities indicates that, before enforcement of the Standard Milk Ordinance, the weighted average retail raw milk sanitation rating was approximately 50, the weighted average raw milk to plant sanitation rating was 37, and the weighted average pasteurized milk rating was 44. After enforcement of the Standard Milk Ordinance for an average of less than 2 years, the weighted average rating for raw milk showed an improvement of 50 per cent, raw milk to plant showed an improvement of 89 per cent, and pasteurized milk showed an improvement of 68 per cent.

The first rating of these Standard

Milk Ordinance cities indicated that 13 per cent of the milk supply was pasteurized; the last rating indicated that this had increased to 30 per cent. The average increase in milk consumption has been approximately 18 per cent.

In conclusion I wish to say that we have been well pleased in every respect with the operation of the Standard Milk Ordinance program, and feel very grateful to the U. S. Public Health Service

for valuable assistance. We have found many difficulties in our path but none that was insurmountable. Probably the most vexing problem at the present time is assuring trained city dairy inspectors reasonable tenure of office. This is a difficulty of real importance wherever the city officials are elected every 2 years, and it has been customary to change inspectors when incumbent officials are defeated.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., PH. D., AND LEONARD GREENBURG, M. D., PH. D.

Death of Dr. George M. Kober---
The first Chairman of the Section on Industrial Hygiene of the American Public Health Association, George Martin Kober, M.D., died at his home in Washington, D. C., of heart disease, April 24, 1931. He was one of the four to present papers in a "Symposium on Industrial Hygiene" at the Jacksonville Meeting of the Association, December, 1914, at which time the Section on Industrial Hygiene was organized. Dr. Kober has been a member of the A. P. H. A. since 1896, and was made a Charter Fellow in 1922.

Dr. Kober was born at Alsfeld, Rhine Province, Germany, March 28, 1850, and came to the United States in 1866, graduating from Georgetown University School of Medicine in 1873. He joined the U. S. Army as acting assistant surgeon in 1874, and spent 20 years of his professional life with the military service, principally in the West during the Indian troubles.

Dr. Kober was greatly interested in Indian welfare and championed it to the end of his life. He also acquired considerable holdings in land in Modoc County, Calif., which was put to graz-

ing. At the same time, in Washington, he was made President of the Sanitary

GEORGE M. KOBER, M.D.

Improvement and Housing Companies, and was considered a housing expert. When he returned to Washington in 1890 he was made Professor of Hygiene at his Alma Mater and in 1901 became the Dean of the School of Medicine,

which position he held until 1928, when he was made Dean Emeritus and one of the regents of the university. He received the degree of LL.D. in 1906, and Litt.D. in 1923, from Georgetown University.

Just after the beginning of the century he became interested in industrial hygiene through his work in the housing of workers, and in 1902 his student, Dr. C. L. F. Doerhing, made the first survey in America of what, in our modern conception, would be called "industrial hygiene" (*U. S. Labor Bulletin*, No. 44, 1903). This work was done under that venerable Commissioner of the Department of Labor, the Hon. Carroll D. Wright.

Dr. Kober was Chairman of the Industrial Hygiene Section of the International Tuberculosis Congress in 1906. In 1908, while Secretary of President Roosevelt's Homes Commission, he headed a survey of the government industries in Washington, an extensive report of which was published in *U. S. Labor Bulletin* No. 75, under the title, "A Report upon Industrial and Personal Hygiene."

He was very prominent as an organizer and official in professional and philanthropical societies and spread his interest in industrial hygiene through the various ones with which he was connected, such as the Association of American Medical Colleges, of which he was president in 1906, the Association of American Physicians, of which he was secretary from 1907 to 1916, the National Tuberculosis Association, of which he was president in 1915, the 15th International Congress on Hygiene and Demography, which met in Washington in 1912, the Pan-American Scientific Congress (also held in Washington) in 1916, and the medical and charitable organizations of Washington, in which he held practically all offices at some time in his life. He also had

many friends in Europe, particularly in Germany.

In 1916 he gathered a group of investigators and specialists in the field and with Dr. William C. Hanson as co-editor produced the well known volume, *Diseases of Occupation and Vocational Hygiene*. In 1920 he wrote a monograph, *Tuberculosis in Relation to Occupation*, and in 1924 was senior editor of Kober and Hayhurst's *Industrial Health*, which comprised the collaboration of 35 authors. He did practically all of his writing in long-hand and in a fine, closely written, although easily legible style.

According to his obituary in the *Journal of the American Medical Association*, he is said to have been the first to point out the agency of flies in the transmission of typhoid fever (in 1892). He established the Kober Foundation in Washington some 5 years ago. He turned the attention of his last years to his Reminiscences, which were published in two volumes only last year.

For the first few years after the formation of our Section on Industrial Hygiene he continued active in it, only ceasing when sickness in his near kinsfolk (he was a bachelor) and the conservation of his own health compelled him to restrict his activities and remain in Washington, where, however, many will remember him as a genial and kindly counsellor, usually to be found at the Cosmos Club. E. R. H.

A Guide-Book for Safety Education—This 89-page bulletin in paper covers has a foreword by William John Cooper, U. S. Commissioner of Education, in which he stresses the importance of teaching safety in the schools and finding room for the subject, thus:

The proper remedy for an overcrowded curriculum is a continuing survey with prompt exclusion from the course of study of obsolete materials and of everything which may be

learned when needed in other ways or at other times and the inclusion in their stead of materials which must be mastered at a comparatively early age unless pupils are to risk loss of life or suffer the loss of bodily powers which may handicap them throughout life.

The book has been very carefully compiled and intergraded for the primary and intermediate grades and secondary schools. The last portion handles the accident question in two columns, the one entitled "Objectives," and the other "Materials and Activities" for the prevention of automobile accidents, fire, railroad, water transportation, home, electrical, gas, aviation, school, industrial and forest relations. There are similar columns for first aid, and for vocational schools, with a final chapter on extra-curricular activities. There is a selected bibliography including sources of certain free materials, slides and films, but no index or table of contents. The introduction is by Albert W. Whitney, Vice-President in Charge of Education, National Safety Council.—National Bureau of Casualty and Surety Underwriters, New York, N. Y., 1931.

E. R. H.

The Effect of Variations in Relative Humidity upon Skin Temperature and Sense of Comfort—From the Conclusions: The effect of relative humidity upon the sense of warmth is in accordance with the effective temperature concept for dry bulb temperatures between 60° to 80° F. The magnitude of the effect obtained on the average for the four subjects and the investigator was somewhat less than would have been expected from Yaglou's thermometric chart. A difference of 50 per cent relative humidity corresponded, in its effect upon the sense of warmth, with a difference of 1.7° F. in dry bulb temperature at 61–62° F. at a constant relative humidity, and with a difference of 4.0° F. at 70° F. The rates calculated from Yaglou's thermometric chart are 2.5° F.

at 61° F., and 4.6° F. at 70° F. on the average for different humidities.

Relative humidities of 70 per cent and above cause an uncomfortable feeling of wetness at 70° F.—Unichi Miura, *Am. J. Hyg.*, 13, 2: 432–459 (Mar.), 1931.

E. R. H.

The Behavior of Lead in the Animal Organism, II. Tetraethyl Lead—Summary and conclusions:

1. These experiments show that tetraethyl lead is absorbed through the skin.

2. The initial distribution of the lead in the tissues in rapid tetraethyl lead absorption corresponds to that of an oil-soluble material, and indicates therefore that some portion of the tetraethyl lead is absorbed and circulates as such.

3. However, tetraethyl lead is rapidly decomposed by the tissues, including the skin, so that only a small portion of the lead found later in the blood is in the form of tetraethyl lead.

4. As a net result, after a period of from 3 to 14 days, all of the lead in the animal tissues is distributed in a manner characteristic of water-soluble lead compounds.

5. In small dosages the factors of rapid decomposition and low concentration in the blood so interfere with the distribution of tetraethyl lead as such, as to prevent its primary absorption by the nervous system.

6. Even when absorbed as the tetraethyl compound, the excretion follows quantitatively that of water-soluble lead compounds.

7. Tetraethyl lead poisoning is therefore not different from lead poisoning occasioned by other lead compounds.

8. Evidence is adduced showing that tetraethyl lead absorption from gasoline in concentrations not in excess of 0.1 per cent is inappreciable.

—Robert A. Kehoe and Frederick Thammann, *Am. J. Hyg.*, 13, 2: 478–498 (Mar.), 1931.

Treatment of Tetanus, Report of Two Cases—Regarding antitetanus serum there is an unanimity of opinion as to its effectiveness as a prophylactic, whereas some element of doubt has been expressed as to its therapeutic value in certain cases in which the disease is already established. This communication

embodies a report on the treatment of two cases of tetanus with massive doses of antitoxin given within a short interval after admission to hospital. The patients manifested the disease in its most severe form, with a very short incubation period in each case.

The first case was that of a boy, 9 years of age, admitted to the hospital on August 20, 1930, who had run a fish-hook into his thumb 10 days prior. On the 6th day, the symptoms developed with stiffness in the neck and locked jaw, becoming progressively worse until most marked symptoms were present on admission (described). The second case is that of a boy 10 years of age, admitted to the hospital, January 6, 1931, who had been injured in the face by a stick of wood which had produced a small punctured wound. The symptoms began 3 days after the injury, and were typical on the 6th day when admitted (described).

The method of treatment consisted of very large doses of tetanus antitoxin, 2,867,500 units in the first case, and approximately 800,000 units in the second case, given by a continuous intravenous method in which the antitoxin was introduced in a 5 per cent glucose-in-saline solution. It was noted that in spite of the large amounts of protein given intravenously, practically no protein was excreted by the kidney and no damage was occasioned by the tricresol contained in the antitoxin. Both cases recovered, without complications.

The Effect of Irradiation with Ultra-Violet Light on the Frequency of Attacks of Upper Respiratory Disease (Common Colds)—Summary:

1. A group of adult volunteers, numbering 363, was kept under observation from September 29, 1929, to May 31, 1930, a period of 35 weeks, and a vigorous effort was made to secure reports of all cases of upper respiratory disease (common colds).

2. From this number, approximately one-half were selected at random for irradiation, which was given over the first 31 weeks of the period. Mercury-vapor lamps were used and the intensity of erythema-producing rays was measured bi-weekly. The dosage was light to moderate, the individuals being stripped to the waist and exposed, either on chest or back on each occasion, to that dose which, from previous experience with the subject, seemed likely to produce only a minimal erythema.

3. Total incidence for the period was slightly higher for the irradiated (receiving more than 10 treatments) than for the controls. Also cases of a more severe type, as evidenced by absence from duty and confinement to bed, by occurrence of fever, by productive cough or by long duration, were just as frequent in the irradiated as in the control group.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Observations on the Assay of the Antineuritic Vitamin—It has been shown that since rats will develop signs of polyneuritis with a small amount of the antineuritic vitamin in the diet it appears that the symptoms of polyneuritis in rats may indicate an insufficient amount of the vitamin rather than its complete absence.

In the experiment here reported diets of various composition were used with a view to ascertaining which were the most favorable for the production of polyneuritic symptoms in rats. A table is given showing the composition of the different diets and the number of rats showing polyneuritic symptoms.

Tests were also made in which six antineuritic concentrates were injected subcutaneously or intraperitoneally. The results show that as the dosage approaches the minimum curative amount some of the animals will be cured and others will not. In this experiment, some of the rats were cured after 5 or 6 previous attempts, and 1 rat was cured after the 11th attack.

Other investigators have succeeded in curing rats that had had more than 2 attacks and others have reported cures after the 6th attack. However, it would probably not be safe to test a preparation on a group of rats all of which have had more than 2 or 3 previous attacks.—W. H. Sebrell, E. Elvove, *Pub. Health Rep.*, 46: 917 (Apr. 17), 1931.

The Unsaponifiable Lipoids of Lettuce. I. Carotene—The purpose of this report is to record a few observations upon the properties of carotene and to present further proof of the vitamin A activity of this substance from lettuce. During an investigation of the

unsaponifiable lipoids of lettuce some brilliant, red, pleochroic crystals separated from a methyl alcohol solution. These crystals proved to be carotene. Approximately 200 mg. were isolated from 10 kilos of dried lettuce, representing 140 kilos of fresh leaves. Carotene crystallizes in the hexagonal system. Carotene solutions may be bleached by heat, ultra-violet light, and by the presence of autoxidizable fats. The physiological activity of carotene was determined by the curative method.

Rats whose diet had been devoid of vitamin A were used when growth had ceased and ophthalmia was usually marked. Carotene in doses of 0.005 mg. per day was always sufficient, except in abnormal cases, to cause a marked increase in weight and recovery from ophthalmia. Cases which failed to respond to carotene treatment always showed other abnormalities, urinary calculi being often present.

From the growth curves it is noted that most of the cases average 3 to 5 gm. gain per 0.005 mg. of carotene, the amount contained in the ordinary 1 drop dose. An explanation of the unusual physiological and chemical properties of carotene must await further information on the structure of the molecule and on the probable electronic alterations which it may undergo.—H. S. Olcovich and H. A. Mattill, *J. Biol. Chem.*, 91: 105 (Apr.), 1931.

The Antiscorbutic Potency of Apples. II—Previous experiments (*Biochem. J.*, 24: 82, 1930) have indicated that (1) Bramley's Seedling is much more potent in antiscorbutic activity than other varieties tested; (2) there is no indication that the age of the tree,

the soil or the season has any effect on the antiscorbutic activity of the apple; (3) there is little deterioration of the vitamin when apples are stored at 1° C. in the air (cold storage) or at 10° C. in an atmosphere of approximately 10 per cent oxygen, 10 per cent carbon dioxide and 80 per cent nitrogen (the loss being greater in the "gas" stored apples); and (4) heating Bramley's Seedlings in their skins at 115° C. for 50 minutes has little effect. The present paper deals with a continuation of these studies. The varieties tested for antiscorbutic activity were Newton Wonder and Lane's Prince Albert, the first being taken from 15-year old trees and the second from 15- to 20-year old trees. The apples were stored at a constant temperature of 1° C. and weekly tests were made. It was shown that:

1. Newton Wonder apples have a vitamin C content of the order of that of Cox's Orange Pippin, while Lane's Prince Albert falls between the Bramley's Seedling and the Cox's Orange Pippin.

2. Bramley's Seedling apples can be frozen at 20° and stored at this temperature for 4 months without losing appreciably in antiscorbutic activity.

3. Bramley's Seedling apples gathered at the end of July were not more active than the normal apple from the same plantation gathered in October.

4. Bramley's Seedling apples stored at 3° in air for 5 months do not lose any of their antiscorbutic activity.

5. The concentration of vitamin C in the tissue of the apple increases as the skin is approached from the core and is more than 6 times as great in the peel as in the flesh near the core.

—Mary Forrest Bracewell, Franklin Kidd, Cyril West and Sylvester Solomon Zilva.—*Biochem. J.*, 25: 138, 1931.

The Antiscorbutic Potency of Apples. III—In comparing the potency of different varieties of apples, a marked difference between the antiscorbutic activity of the Bramley's Seedling and the King Edward was observed in spite of

the fact that they resemble each other in so many respects. In this experiment an attempt was made to determine whether a relationship existed between the nitrogen content and the antiscorbutic activity of the apple. A table is given showing the tests as carried out. It was found that King Edwards containing about 0.0307 per cent of nitrogen were about 1.5 times as potent in vitamin C as apples of this variety containing about 0.0387 per cent of nitrogen. No significant difference in the vitamin C content was found between Bramley's Seedlings containing high and low quantities of nitrogen.—Mary Forrest Bracewell, Thomas Wallace and Sylvester Solomon Zilva, *Biochem. J.*, 25: 144, 1931.

The Effect of Acidity on Lactobacillus Acidophilus Cultures—From the results heretofore reported it was concluded that *L. acidophilus* milk cultures could be stored at either refrigerator or room temperatures for several days without any considerable destruction of the organisms provided the original acidity was not too high. The results given in this report were obtained upon milk cultures of *L. acidophilus* that were high in acidity when stored. A decrease in the number of organisms took place at an acidity of approximately 1.2 per cent in all but one strain. At higher acidities of approximately 1.5, 1.6, 1.7, and 1.8 per cent, a still greater destruction of organisms took place. The acidity at which this greater destruction occurred varied with the strain. It was indicated that the particular sample of each strain that gave the highest count before storage usually gave the highest count of the series after storage at 9° or 24° C. The results obtained indicated that the acidity at which the maximum number of organisms was secured during incubation of a culture was an index as to the acidity at which to place cultures in refrigerator storage. •

—Luther A. Black and J. C. Harris, *J. Dairy Sci.*, 14: 198 (May), 1931.

The Vitamin A Content of Oats—

This is a report of an investigation made of the vitamin A content of whole hull-less oats and of the acetone-extracted oil of the whole hull-less oats. Rats 28 to 30 days old and weighing 50 gm. were placed on a vitamin A free irradiated basal diet, supplemented with dried brewer's yeast to furnish vitamins B and G. Definite ophthalmia usually developed within 25 to 35 days, at which time ground whole hull-less oats as the sole source of vitamin A replaced the same percentage of starch or Crisco, or parts of both the starch and the Crisco in the diet. The test period was 8 weeks. It was found that whole hull-less oats are almost if not totally lacking in vitamin A, and death occurred when whole oats were fed at levels of from 0.6 to 5 gm. daily. When acetone-extracted oat oil was included in the diet, the condition of the animals was slightly improved. All but one animal lived throughout the 8-week period but growth was very slow or completely arrested.

From these results it is concluded that oat oil contains a small amount of vitamin A. When 8 drops of cod liver oil was given, ophthalmia was completely cured in 7 to 14 days, which indicated that the poor condition of the

animals was not due to a toxic effect of the supplement but to a deficiency of vitamin A in the oat oil.—Clara R. Meyer and Rossleene Arnold Hetler, *J. Agri. Res.*, 42: 501 (Apr. 15), 1931.

Utilization by Normal Adult Subjects of the Calcium and Phosphorus in Raw Milk and in Ice Cream—The subjects used in this experiment were 10 normal adults, 5 of whom were irradiated daily for a period of 5 minutes at a distance of 30 inches from the arc. The diet, which was somewhat acid-forming, as is common throughout this country, consisted of ground lean round of beef, white bread, polished white rice, raw apple, orange juice, prunes, and oleomargarine. The variables of the diet were ice cream and raw milk. It was found that for the non-irradiated subjects, the calcium of ice cream gave the more favorable balance, while for irradiated subjects, the calcium of fresh milk was slightly better. The non-irradiated subjects showed calcium balances at least as favorable as those of the irradiated subjects. The non-irradiated subjects also showed somewhat better phosphorus balances than the irradiated subjects, but practically no differences appeared between the milk and ice cream periods.—Martha M. Kramer, Myra T. Potter and Isabelle Gillum, *J. Nutrition*, 4: 105 (May), 1931.

CHILD HYGIENE

RICHARD A. BOLT, M. D., DR. P. H.

CHILDHOOD tuberculosis is commanding a great deal of attention at present. Almost every medical and public health journal of recent date contains one or more articles upon some phase of this subject. It is common knowledge that there has been a steady and consistent decline in mortality from tuberculosis during the past two or three decades. While this has been most marked in countries where intensive public health work directed against tuberculosis has been carried on, it is none the less true that a decline is noted also in other places where very little, if any, concerted effort is expended in controlling this disease.

In the United States a considerable decline in tuberculosis death rates has taken place at all age levels, being most marked in childhood, and among males between 20 and 45 years of age, and showing the least reduction in females between the ages of 15 and 20.

In 1923, Dublin¹ predicted that a tuberculosis death rate of 50 per 100,000 population would not be far from the actual figure in the year 1930. While the rate for the whole Death Registration Area has not yet reached that figure, it is tending toward that rate and in a number of individual places has actually reached it. What Dublin stated then is just as true today:

The tuberculosis movement must not rest on its laurels nor be allowed to drift along easy ways. The disease is on the decline. This is an opportune time to apply even greater energy along approved lines, that there may be no diminishing but rather cumulative returns in life saving.¹

During the period under consideration much research has been directed

along lines of childhood tuberculosis. The more recent investigations have altered considerably our conception of tuberculosis in children and its relation to adult tuberculosis. Our emphasis of the relative value of the various means of diagnosis has shifted and a new classification of the types of tuberculosis has replaced the old. The extensive use of the tuberculin test and more refined technic in the manipulation of the roentgen rays in the diagnosis of childhood tuberculosis have given us a more definite and clear-cut picture of the disease.

It has been noted for some time that the morbidity from tuberculosis and the mortality do not coincide. The results of tuberculin testing reveal varying percentages of positive reactions depending upon age, opportunities for infection, type of community, racial factors, etc. During school age the death rate from tuberculosis is relatively low while the infectivity as shown by tuberculin tests is high. Myers² in his new book, *Tuberculosis Among Children*, devotes a whole chapter to consideration of the incidence of tuberculosis in children. The chapter is summarized as follows:

1. Tuberculous infection in this country is by no means universal among children.

2. The incidence of infection among school children has been found to vary from 10 per cent to 90.2 per cent depending upon the opportunities for exposure to tubercle bacilli.

3. The tuberculosis of a community is reflected in its children.

4. Tuberculin tests applied to all children of a community is the best method of approaching the tuberculosis problem. Among the positive reactors will be found children with tuberculous disease, and among their adult associates will be found open cases of tuberculosis previously unrecognized.

Myers also points out clearly that tuberculosis is largely a family disease, and that its prevention in childhood must begin in the family group.

When tuberculosis exists in the family, the infant should be separated from the tuberculous member as soon after birth as possible. This should be accomplished before infection has occurred, but if the child has already been infected, the separation should be provided for at the earliest possible time. Contrary to a rather general belief the infant who reacts positively to the tuberculin test is in danger from further infection. Every physician should test rather frequently with tuberculin each infant under his care, and if possible make X-ray studies of the chests of the close associates.

Pasteurization of the milk is emphasized as well as avoidance of adult infection. Everyone interested in this recent work with childhood tuberculosis should read Myers's book from cover to cover. At the end of each chapter are references to original sources.

As an excellent companion to Myers's book one should have at hand the convenient brochure, *Childhood Type of Tuberculosis*, by Chadwick and McPhedran, published as diagnostic aids by the National Tuberculosis Association.⁷ The childhood and adult types of tuberculosis are clearly differentiated. The diagnosis depends upon the history, symptoms, physical signs, tuberculin test, X-ray evidence and the exclusion of other causes that might produce similar conditions. It is emphasized that the diagnosis of childhood tuberculosis cannot be based upon any one sign or symptom.

Many children have the childhood type of tuberculosis without manifesting any symptoms that can be ascribed to the disease, although they may have a progressive lesion. . . . The tendency to tire easily is often noted and may be said to be the most common symptom in these children.

These authors, as most of the modern workers in the field of childhood tuberculosis, lay most stress upon a care-

ful history, the tuberculin test and the roentgenogram.

According to these authorities,

A positive reaction to the tuberculin test always means infection with tubercle bacilli, but it does not necessarily indicate disease, or whether it is active or latent. The Mantoux or intracutaneous test is more accurate, and with it a slightly larger number of reactors will be obtained than is possible with the Pirquet technic.

Referring to the value of the X-ray it is stated:

A roentgenogram is indispensable in the examination of a child's chest. Without it a positive diagnosis of the childhood type of tuberculosis cannot be made. Furthermore, a physician, however good a clinician he may be, is not justified in excluding tuberculosis without checking his physical examination of the chest with the evidence that only an X-ray film can give.

Chadwick has shown also that weight as an index of tuberculosis is fallacious. In either the childhood or the adult types of the disease we may find underweight, average weight or overweight children. If we take only the underweight children many cases of childhood tuberculosis will be missed.

Tuberculosis is particularly insidious in young women from 15 to 20 years of age. At this period any undue strain may cause a childhood type of tuberculosis to take on the characteristics of the adult type. A number of recent studies have been made which show that the adolescent years are especially dangerous, and should therefore be protected against any severe stresses or strains.

A survey of tuberculosis in certain schools in Colorado⁸ brings out some very interesting points:

1. The statistics for the mortality and morbidity of tuberculosis in children today and 10 years ago are not comparable.
2. The number and size of positive reactions increase in children commensurate with contact and the age as noted by Dickey.
3. The incidence of tuberculous infection among children varies greatly in different parts

of the country and is influenced by climatic and other environmental factors.

4. A survey for tuberculosis in the school of a good community composed largely of health seekers, when contact with the disease is unusually great, showed 36.4 per cent of 283 children from 4 to 15 years of age to be infected. This is only a moderate increase over the incidence noted in non-tuberculous communities.

5. Roentgen studies of the 103 children giving positive reactions revealed childhood tuberculosis in 19 or 6.7 per cent of the whole group. An average for the country at large varied from 1 to 4 per cent.

6. No child with the adult exudative type of tuberculosis was found.

7. Most of the children reacting positively and those having active childhood tuberculosis were not born in Colorado.

8. Climatic factors in Colorado apparently exert a favorable influence in the protection of children against active tuberculous infection.

9. In this study the father was the source of infection in 64.8 per cent of the children giving positive reactions and mothers in only 12.6 per cent.

10. Symptoms of fatigue, undernourishment and a history of frequent colds are not reliable aids in the diagnosis of childhood tuberculosis.

The practical conclusion to all this discussion is that every community should make ample provisions for the tuberculin testing of its childhood population and for the proper follow-up with X-ray examinations.

Sex Education in Childhood

THE May issue of *Child Study* is given over entirely to the consideration of sex education in childhood. It contains a number of informative articles on various aspects of sex in childhood by such well-known authorities as Marion Kenworthy, Leonard Blumgart, Mrs. Cecile Pilpel, Floyd Dell and Dr. Charles W. Margold. In the editorial introduction Marion Kenworthy aptly states:

Sex education of an ideal sort can only be accomplished through a consistent constructive handling of the parent-child relationships. . . . The most effective way to spread this important educational movement is through active work with parents; for the emotionally balanced child of today is the mature parent of tomorrow.

The Parents' Rôle in Sex Education is clearly presented by Dr. Blumgart. Among other important points in his well balanced article he states:

Just as children use their parents as models in all other spheres, so also are they models in their sex life, though perhaps in a more subtle but no less significant way. It is, therefore, most important that parents should understand the growth and development of the sex drives in human beings.

There is also in this interesting issue a brief discussion by Dr. Bernard Glueck of Sigmund Freud's criticism of society.

There appear the usual parents' questions and discussions, book reviews, and news items.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

How Much Nurses Knew about Obstetric Nursing in 1930 as Revealed by a Survey Made by the Subcommittee on Obstetric Teaching and Education of Nurses and Nursing Attendants of the White House Conference on Child Health and Protection—Graduates of hospital nursing schools are doing obstetric nursing in hospitals as "special," "head," or "staff" nurses, and in homes as "private duty," "hourly," "visiting," or "maternity and infant hygiene" nurses.

What Nurses in these Positions Are Being Asked and Expected to Know How to Do:

1. Find pregnant mothers and teach them their need for medical care during pregnancy and persuade them to go to a doctor
2. Give instruction to fathers and mothers individually and in class groups about
 - (a) The mother's hygiene during pregnancy and how it may be fitted into the daily régime of the home
 - (b) Preparation for the baby, including his bed, his toilet supplies and the care of them
 - (c) Preparation of delivery supplies and a plan for the mother's care during delivery and the lying-in period
 - (d) Care of the baby, including his bath, his rest, his exercise, his food and his daily régime in relation to the needs of the family
3. Observe and question the mother to learn about symptoms and discomforts needing attention—including simple urinalysis and measuring the systolic blood pressure
4. Study the mother's home surroundings and family relationships so as to discover—and help to solve—any problem which in any way may disturb her peace of mind
5. Consider the health of every member of the family—teaching the fundamentals of per-

sonal and home hygiene and arranging for health examinations, the correction of defects, the following of treatments or advice

6. Help the doctor or midwife during labor and delivery

7. Give—or teach some responsible person to give—the necessary care to mother and baby during the days that follow

8. Teach the family why a well baby needs continuous medical supervision and why a mother needs an examination by a doctor after the baby is 6 weeks old, and help to arrange for them and for further care when that is indicated

9. Keep the doctor of hospital informed by sending a detailed report of each visit including findings and advice

How the Nurses Questioned Were Chosen:

There were three groups of them:

1. Private duty nurses registered in 1930 for obstetric nursing in the 93 Nurses' Official Registries—each registrar was asked to send the names of 10 nurses to whom the questions could be submitted.

2. Nurses graduating from schools of nursing in 1930 and taking the state board examinations in the summer months. Each board of examiners was asked to present the questions to its applicants, with the request that they be answered, not for credit, but as a contribution to the work of President Hoover's Conference.

3. Nurses taking postgraduate courses in public health nursing in 9 universities in 9 states, and writing examinations in the summer of 1930. The directors of the courses presented the questions as supplementary to their examinations in much the same way as the state boards of examiners did to the second group.

These Were the Two Questions Asked:

1. State what you consider constitutes complete care for a mother from the beginning of pregnancy until the baby is 6 weeks old (29 items in the detail of that care were listed for the nurses to check).

2. How can maternal mortality be prevented?

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

Conclusions from the Returns:

Sixteen hundred and twenty-two nurses returned their answers to these two questions. Only 17.9 per cent mentioned a physical examination and continuous medical supervision during pregnancy as an essential element in adequate maternity care; 24.9 per cent mentioned an aseptic delivery; 8.7 per cent postpartum medical care; and only 5 per cent postpartum nursing, to give only a few of the figures. It was clear that the nurses did not know what adequate maternity care is.

A large number of nurses did not even answer the question about preventing maternal mortality. Some answered it in a way to indicate they had no idea what maternal mortality meant.

And so we must conclude that, with few exceptions, nurses do not know that many of the deaths of mothers in childbirth can be prevented, that obstetric nursing plays a part in that prevention or that the great number of those deaths in this country is a national problem that challenges every doctor, nurse, and health worker who comes in contact with pregnant mothers.

Where the Public Health Nursing Group Stood:

The best answers to the questions came from the students in a postgraduate course in public health nursing who had recently attended an institute in obstetric nursing.

CONCLUSION

This hasty study has shown that the teaching of obstetric nursing has been inadequate. Just how this situation can be improved will have to be worked out by a committee especially interested in maternity care and

... qualified to develop methods for and to stimulate the adoption of better teaching of obstetric nursing. Such a committee would need funds and a full-time secretary who should be a nurse who knows obstetric nursing. Such a committee should work closely with the National League of Nursing Education and the Committee on the Grading of Nursing Schools to avoid duplication of effort.

It will be some time before the work of such a committee can be finished. In the meantime those improvements that can be stimulated by an appeal from the White House Conference to all hospital trustees, medical boards, superintendents, directors of nursing, boards of nurse examiners and nurses' associations should be encouraged.—

Next month we will give a summary of the recommendations of this committee. —The White House Conference on Child Health and Protection. Excerpts from the Report of the Subcommittee on Obstetric Teaching and Education of Nurses and Nursing Attendants, *Am. J. Nurs.*, XXXI, 5: 581-585 (May), 1931.

This Official Health Agency Has a Completely Generalized Program—Memphis, Tenn., is unique in that the Health Department nursing staff, numbering 40, carries on an almost completely generalized public health nursing service. Two nurses do delivery service and another nurses the major communicable diseases in the homes. The program of the nursing service includes bedside nursing care as pay, part-pay and free service, school nursing, child hygiene, preschool, prenatal and postnatal care, tuberculosis and communicable disease nursing. It is paid for entirely by taxation. The fees collected for nursing care and delivery service go into the city treasury and do not alter the budget of the Division of Public Health Nursing.

Health Department nurses lend assistance to private physicians at deliveries where a fee of \$5 is paid for the first 4 hours and \$1 for each succeeding hour. These nurses also assist with all cases delivered by the out-patient department of the City Hospital. The two delivery nurses and another nurse from the Health Department assist with the prenatal clinics of the out-patient department of the City Hospital which are under the department of obstetrics in coöperation with the University of Tennessee.

All calls for the delivery nurses of the Health Department are handled by the City Hospital telephone exchange operator. The bag equipment for private as well as out-patient cases is furnished by the maternity department of the City Hospital. All cases are referred to the Health Department nursing staff for prenatal and postnatal care.

This generalized nursing program, completely tax supported, grew out of a survey of the city's health and hospital facilities made in 1924. A second appraisal of the health and hospital facilities was made in 1930. The following is a quotation from the report of the last survey:

Since January 1, 1926, the number of cases delivered by the Out-Patient Department has shown a 100 per cent increase, but the most marked increase has been among cases for private physicians which at the end of 1929 increased to a number five times as large as the number delivered in 1926. The average number of deliveries per month for 1929 was about 25 for private physicians and about 50 for the Out-Patient Department. The large number of births occurring in hospitals in Memphis reduces proportionately the responsibility of the Health Department for a home delivery service; in 1929, 55 per cent of the total births occurring in hospitals, 67 per cent of the white and 38 per cent of the colored (84 per cent of all colored births were registered at the Out-Patient Department prenatal clinics).

The Memphis Health Department Division of Public Health Nursing now feels that the main objective of their maternity program should be to find prenatal cases earlier in pregnancy, get them under competent medical supervision earlier and increase the number of visits per case.—Bride L. Cawthon,

Delivery Service in an Official Public Health Agency, *Pub. Health Nurse*, XXIII, 5: 235, 236 (May), 1931.

Miss Gardner Wins the Saunders Medal—At a meeting of the Advisory Council of the American Nurses' Association in Atlanta, Ga., May 4, it was announced that the Walter Burns Saunders Medal Committee had been unanimous in its selection of Mary Sewall Gardner of Providence, R. I., as the recipient of the medal for distinguished service to her profession.

Miss Gardner is probably best known to the rank and file of public health nurses through her book *Public Health Nursing* which has been translated into several languages and which is known as the standard textbook in public health nursing throughout the civilized world. It was not this book of Miss Gardner's which influenced the Medal Committee, however, as writing was the only service excluded in determining who should receive the award. Miss Gardner for the past 20 years has been closely identified in her professional career with the dramatic development of public health nursing. Her colleagues call her the "dean of public health nursing."

The Saunders Medal Committee announces that application for the 1932 Saunders award may be submitted at any time during the coming months. Rules for eligibility were given in the Public Health Nursing Section in the April, 1930, *American Journal of Public Health*.—June *Bulletin* of the American Nurses' Association, 1931.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Next Is Montreal!—For those concerned with any phase of public health education Montreal is the next source of ideas and information.

The Public Health Education Section members' dinner Monday night will take up several questions of vital interest touching health education progress.

Radio, amateur movies and exhibits will have a session.

A half day will be given to high school health instruction.

Canadian health workers will entertain and instruct at a luncheon.

And one luncheon session will undertake to answer all of the unanswered questions!

What question would you like to have answered?

What question would you like to answer?

Please tell the editor of this department.

Racine Listens In—Most figures as to the number of radio listeners are guesses, but Racine tried for facts.

In the week of May 11 to 16, Health Department nurses were instructed to inquire at each home where they made a call, whether or not the family was in the habit of listening to the Health Department radio programs, inaugurated April 1, 1931. These calls were not made for the purpose of checking up on radio, but were the regular calls made by nurses for other purposes. They represent all parts of the city and all educational and economic levels without selection.

The question asked was simply whether the family was in the habit of listening to this program. They were not asked how they liked it, because we felt that many of them

would be disposed to be courteous and to say that they liked it, even if they did not. The figures follow:

No. of homes at which nurses called	564
Homes without radio	133 (23.6%)
Homes with radio	431 (76.4%)
Homes in the habit of listening to Health Department program	186 (33.0%)
Homes not in the habit of listening to Health Department program	245 (67.0%)

If we apply these percentages to the entire city, we get the following figures:

Total number of homes	14,000
Number without radio	3,140
Number with radio	10,860
Homes with radio not getting our program	6,180
Homes with radio and getting our program	4,680

Discounting this last figure 50 per cent as a margin of safety we feel safe in estimating between 2,000 and 2,500 homes getting our message.

Of course, the latter part of this letter goes deeply into the realm of speculation but it is interesting and I know of no other way to estimate a radio audience. At least we are satisfied that our effort is worthwhile.

—W. W. Bauer, M.D., Commissioner of Health.

International Hygiene Exposition—Happily Dresden will continue its great health show through the summer of 1931. Further information may be secured through Dr. Rudolph Woerner, Room 835, 1775 Broadway, New York.

Readers of this department who visit Dresden may secure capable guide-interpreters at low cost. The editor will be glad to supply letters of introduction to staff members of the German Hygiene Museum, which is the central and permanent feature of the Exposition.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Will They Do It?—What about the men or the women or the youngsters whom you expect to read your printing—will they do it?

Yes, if you compel them to. The only way in which you can compel them is through the first impression they form the minute they receive your printed matter . . . call it attention-value, or what you will, you willingly admit that first impressions come through appearance. . . . Appeal to the eye in any form of sales promotion, is always a matter of printing, for modern printing is a great deal more than type, paper, and ink. . . . It is design, colors, size, style, the right type, and the right paper. It is possessing sound knowledge of how to print so it will be read and applying that knowledge to production. . . . Will they do it?

—From house organ of Speaker-Hines Printing Co., Detroit.

A Mother's Library—Do department stores in your city distribute or loan publications on the care of infants? This idea is fostered by *Infants' and Children's Department* (1 E. 35th St., New York), which says (May, 1931):

A reference library for mothers is a tremendous potential factor in the building of business in infants' departments. The early departments for the most part felt that the loaning of books to mothers was an essential part of education. They found that it helped the department materially. They knew that infant welfare is largely a matter of education; and that the store which does the best job of educating stands the best chance of getting the business. Today, the idea of service is not so much emphasized. Certain outstanding books for mothers on motherhood and babyhood are available to stores for loaning purposes. Lending these books to mothers, without charge, tends to build in a mother's mind the belief that the store has her welfare at heart. The outlay for the books is small; the good accomplished by the loaning is great. . . . Lending a book is indeed a small gesture, but one that mothers accept gratefully. Most of them do not know what to ask for or where to look for it, even if they desire to have all possible information on subjects which so vitally concern them.

This points to another example of the

many worthwhile jobs which usually cannot be touched for lack of time. *But it is a job for volunteers.* The out of date or definitely undesirable may now be used in some stores. Other stores might become interested in the idea and have a welcome for suggestions. Sales people in specialty and department stores having infants' and children's departments hear much about the problems of mothers. It is important that they know good publications to mention, and have good material to distribute when they undertake this service.

A tactful committee of one, two or three women could be enlisted by the health department or association to check up on what is now in use and refer lists to a competent authority for comment. The committee might go armed with copies of a small, selected list of books, pamphlets and magazines.

The page from a copy of the magazine mentioned above might be desirable. It is *free*.

"To Have and To Hold"—Under this title (*Survey*, 112 East 19th St., New York, May 15, 1931. 30 cents), Arthur Dunham tells how to handle one's personal collection of professional reference material—"notes, memoranda, manuscripts, clippings, reports." The 5 steps outlined apply equally well to the office collection of the public health worker who has no elaborated filing classification—and to the health education worker until that time when we have a topical classification on either school or public health education.

Suppose we start with cutting up the *Journal*—all the articles containing references to health education and all of the topics appearing under "Education and Publicity." We will want to subscribe for an additional copy of the *Journal* or beg the "Education and Publicity" pages from a coworker to have both sides of the pages.

Requested: the classifications used by some of our collectors of health and health education information.

Not Among Those Present-- Schools of Law, Schools of Medicine, Schools of Veterinary Medicine, Schools of Osteopathy, and others are listed but—as is the custom—schools of public health are not listed in Institutions of Higher Education, an official publication of Office of Education, Dept. of the Interior. Page Prof. C. E. Turner!

CHILDREN AND SCHOOLS

"The Nurse in the High School," by A. G. Ireland, M.D. (includes health education); "The Health Counsellor in High School," by C. M. Simon, R.N. *Public Health Nurse*, 450 7th Ave., New York. Oct., 1930.

"A Puppet Show," by C. A. Hammond. *Hygeia*. June, 1931. Details and "The Health Brownies Help" in full—as given by school children. Puppets are good for all ages.

"Summer Health Schools" (in Los Angeles County) by Alma Overholt. *Hygeia*. June, 1931. 6 illus.

"Teaching Housing to School Children," by Bleeker Marquette. What an 8th-grade course aims to do. *Journal of Home Economics*, Baltimore. June, 1931. 30 cents.

"Teaching Topics on Narcotics." *Journal of Natl. Education Assn.*, Washington. Feb., 1931. Reprint. 10 cents.

"What Can the Volunteer Agency Do to Assist State Departments of Education to Obtain Adequate Supervision of Health Teaching?" by J. E. Rogers. 8 pp. Reprint. Natl. Tb. Assn., 450 7th Ave., New York. Free.

School Hygiene Handbook—Division of Child Hygiene, Massachusetts Dept. of Public Health. 95 pp. A working manual—crammed full of detailed procedures, blank forms, condensed facts—numerous addresses given in full—index

and date! The good outline of publicity is so condensed that it lacks the detail for easy use by those more familiar with procedures in other directions. As it happens no information source is mentioned. Does not the Child Hygiene Division supply ideas or forms for some of the suggested publicity material?

Edited by Iago Galdston, M.D. Most of the contents useful in other cities. Free to health officials.

HONORABLE MENTION

To Department of Health, New Brunswick, Canada: for annual report with detailed table of contents.

To Quebec Provincial Bureau of Health: for yearly table of contents (two languages) of *Bulletin Sanitaire*.

CAMPAIGNS

"Doctors Here Open Health Test Drive—County Societies Join in Five-Year Campaign for Preventive Examinations—To Use Films and Radio—Welfare and Civic Groups Will Be Asked to Coöperate in Program of Public Education"—thus the *New York Times*. April 26, 1931. The Greater New York Health Examination Committee is located with the Academy of

Medicine, 2 E. 103d St., New York.

A 3-months campaign in education on syphilis and gonorrhea is reported in *An Educational Experiment in the Bellevue-Yorkville District of New York City*, by Savel Zimand. A reprint from *Journal of Social Hygiene* (March, 1931) will be supplied by the author at 325 E. 38th St., New York, who says:

Ours was merely an experiment—a beginning. We have learned a great deal from it. We hope it will be taken up by others.

Empire Health Week is reported in *Mother and Child*, London, as having been celebrated from Bath to Bagdad. Started in the United Kingdom in 1912 it has spread to Australia, New Zealand, India, Africa, Canada, and elsewhere.

Glimpses of Roll Call campaign ideas were given in *Red Cross Courier*, Washington, for Oct. 15, 1930. "The Diary of a Roll Call Chairman" brings Mr. Pepys down to date in the guise of a 1930 Red Cross chairman. Clever and stimulating.

If you have a malaria campaign ahead you will wish to look up the illustrations for "Mosquito Propagation" in *Municipal Sanitation*, 24 West 40th St., New York, Jan., 1931. 15 cents.

CONVENTIONS

School or popular health education topics are being found on many convention programs. Some recent examples:

"The Health Education Service of the Department," by Mary Power—Ontario Health Officers' Assn.

"Aids in Child Health Education," by T. J. Werle, Michigan Tb. Assn.—Illinois Tb. Assn.

"Health Education," by Saidie Orr-Dunbar, Ira V. Hiscock, H. J. Sears, Catherine S. Bastian, Arlien Johnson—Western Branch of A. P. H. A.

"Publicity in Health Education," by A. E. Wells, Manitoba Dept. of Health and Public Welfare—Canadian Public Health Assn.

"The task of national Red Cross So-

cieties in organizing and conducting campaigns to protect communities against tuberculosis, etc."—Third Pan-American Red Cross Conference.

The Connecticut, Rhode Island and Massachusetts Societies for Mental Hygiene sponsored a New England Conference on Mental Hygiene in Education, May 1 and 2, 1931.

The recent first conference of state mental hygiene societies in New York devoted one afternoon to educational and publicity topics.

The chief meeting of the season on school health education will be the section on this subject in the World Federation of Education Assns., Denver, July 27–Aug. 2. Address: Sally Lucas Jean, 200 5th Ave., New York.

If you have failed to see the folder, Why I Attend Annual Meetings, be sure to ask the A. P. H. A. for a copy.

DIPHTHERIA

Pau Diphtheria, Board of Health, Hawaii, is "the story of Honolulu's campaign." An insert "For Mainland Readers" interprets the title: "Put an end to Diphtheria"! And the report tells how nearly that was done by the use of 8 languages and many activities.

"New York City's Diphtheria Campaign," by E. F. Brown. *Quarterly Bulletin*, Milbank Memorial Fund, 49 Wall St., New York. Jan., 1931. Free. Review of the N. Y. City campaign.

Mass movements are necessary in the early stages of any new idea. Very few of us do any of the things we do by sheer force of intellect. Many of us know that we eat far too much and that two meals a day would be much better for us than three; however, when everyone else is going to the dinner table it creates a situation that makes even the most obese conspicuous unless he likewise gathers around the festive board. The same might be said of the styles in women's and men's clothing. We wear furs about our necks in July and go with our necks bare in January not for any real intellectual reason but be-

cause those in the orbit in which we wish to appear are doing it. Need I go further with illustrations of the sheep-mindedness of the human race? The street ballad "Everybody's doing it" is about as good a reason as most of us can give for many of the things we do.

As public health workers we should take advantage of this characteristic of the human mind and utilize this tendency to move *en masse* in the promotion of a sound public health program. To test out the importance of utilizing the mass movement in diphtheria prevention work, a former state health commissioner in Ohio set aside two counties for an experiment. He had the counties canvassed by lecturers, and public health nurses, distributed printed matter as near as possible, and carried on a modern diphtheria prevention campaign except that instead of utilizing the mass movement of the community, parents were *told* to take their children to the family physicians to have them immunized. Diphtheria immunization in these two counties was to be a single and individual service of the physician to the patient, without the element of mass movement being involved. At the end of a year of this type of work, careful surveys were made of the entire county which showed conclusively that slightly less than 2 per cent of the children were immunized. In the adjacent counties where the same methods were used and the impetus of mass movement in public health was tried, 95 per cent and 98 per cent of the average daily attendance at the schools were found to be immunized. Could a better picture of the importance of mass movement in public health work be required? When a piece of public health work is absolutely new, and the idea is falling on untilled soil, perhaps a campaign is the proper way to approach the problem.

—D. M. Griswold, M.D., in *Illinois Health Quarterly*, State Dept. of Public Health. January–March, 1931. Next month we will quote further from Dr. Griswold—some questionings as to campaigns.

RADIO

Every health and social agency using the radio should study "Advertising by Radio" by Orrin E. Dunlap, Jr., radio editor of the *New York Times* (Ronald Press, New York. 186 pages. \$4.00). There is no direct instruction for the health or social worker, but numerous

indirect suggestions and much valuable information. Note this: "Simplicity is what counts. . . . The radio audience care nothing for 'hifalutin' words. Talk in language everyone can understand." Check this advice with some of the selections from radio health talks which have been quoted under "Words" in this department.

Devils, Drugs and Doctors, weekly radio talks by H. W. Haggard, M.D., are supplied upon request in perforated loose-leaf form, by Eastman Kodak Co., Rochester, N. Y. Why are so many thousands of hearers so interested that they write for copies of these broadcasts?

He who plans a local series of broadcasts (or brief newspaper releases) on health superstitions will find useful material in *Hygeia*, including "Ghosts and Gods, Astrologers and Miracle Men," by Otto Neustätter. June, 1931. Illustrations from International Hygiene Exposition.

A radio course in mental hygiene is based on a series of 8 broadcasts by Dr. H. B. Elkind, Massachusetts Society for Mental Hygiene. Radio audience students register by sending \$1 to State Division of University Extension, State House, Boston. They receive printed information on which each lecture is based and instructions for required home work.

"A Revealing Smile" (5 minutes on mouth hygiene). *Connecticut Health Bulletin*, Hartford, Jan., 1931.

"Getting Along With People"; "Those Human Spark Plugs"—Connecticut State Dept. of Health.

"The Great Unknown" (mental hygiene); "A Legend of the Great East Gate" (germs); "Measles Is a Dangerous Disease"—New York State Dept. of Health.

"The Mechanics of Smell"; "What People Believe"; "Man's Marvelous Machinery"—broadcasts by American Medical Assn.

"Fatigue and Worry"; "Fatigue and the Blues"—Public Charities Assn. of Pennsylvania, Philadelphia.

"Some Fundamental Principles of Child Training" is a radio topic announced by a health agency. *Will someone re-write the title so that parents will be inclined to tune in?*

One wonders who tuned in on a recent radio talk on "Hygienic Adjustment Throughout Life"?

Debates, speakers, music, comment on current problems, and answers to questions from the radio audience make up the weekly program of the very successful radio Community Forum of the St. Louis Community Chest. To be studied by a group of health agencies, or health and social agencies ready to invest generously in brains and time. Annual report *free*.

Much information about education in general by radio is available upon request to Office of Education, Washington, D. C., and National Committee on Education by Radio, 1201 16th St., N.W., Washington, D. C.

Illinois Society for Mental Hygiene broadcasts through Station WMAQ, Monday, 5:45 p.m., C. S. T.

Minnesota State Medical Assn. broadcasts over WCCO, Wednesday, 11:45 a.m.

MAGAZINE ARTICLES

"The Family Doctor," by Dr. Winford H. Smith. *Saturday Evening Post*. May 16, 1931. The complicated cost of medical care.

"How to Pick a Doctor," by C. Houston Goudiss. *Literary Digest*. May 30, 1931. From *The Forecast*, New York. Well worth looking up.

"The Right to Drive," by R. S. Kirby. *Atlantic*. April, 1931. Automobile accidents largely due to lack of concentration, caution, consideration.

"The Slender Waist: How to Regain It," by Dr. G. F. Alsop. *Woman's Journal*, 171 Madison Ave., New York. March, 1931. Includes simple exercises.

BOOKS AND REPORTS

The Principles of Epidemiology and the Process of Infection—*By C. O. Stallybrass, M.D., D.P.H. New York: Macmillan, 1931. 696 pp. Price, \$8.50.*

We have here an exceptionally good book, following in many respects new lines. While we cannot entirely agree with the definition of epidemiology given, we are not inclined to find serious fault with it, though it seems to have furnished the reason for burdening the text with some material which might have been better treated elsewhere.

Chapter III, of 47 pages, is devoted to statistical methods, the understanding of which is doubtless of value to every health officer, but which we believe has no place in a book of epidemiology. In a number of other places, statistical material is brought in, and Appendix I is a table for calculating probable error. Appendix II gives the classification of pathogenic bacteria and there is some discussion in the body of the book on bacteriological and mycological classification and nomenclature which it seems to us might well have been omitted. We are doubtful concerning the propriety of including the long discussion of specific resistance in which we find several of the leading theories of immunity, anaphylaxis, etc.

The greater portion of the book, which is devoted to what is really epidemiology, is unusually good and well put, and may be regarded as a series of masterly essays which show deep study and wide experience.

Without any desire to lessen the credit of Semmelweiss, we must point out the well known fact that the credit of having first called attention to the contagious nature of puerperal fever belongs to Oliver Wendell Holmes, who

in 1843 wrote: "The disease known as Puerperal Fever is so far contagious as to be frequently carried from patient to patient by physicians and nurses."

There are some omissions such as that of the name of Agramonte from the United States Army Commission appointed to study yellow fever. A number of misprints of proper names also occur, as Desonbry for Desoubry, Lazcar for Lazear, and B.C.G. for BCG.

The book is primarily intended for the medical officer of health and is written from the English standpoint, though American and other foreign authors are fairly treated. In addition to his own extensive experience, the author has availed himself of the assistance of several noted bacteriologists and epidemiologists.

The book ends with a fairly good bibliography and index of authors, as well as a subject index. Altogether we consider it one of the best books for its purpose which has come to our attention. It is attractively written and well illustrated with charts, diagrams, and a few colored plates. M. P. RAVENEL

The Physical Basis of Personality—*By Charles R. Stockard. New York: W. W. Norton & Co., Inc., 1931. Price, \$3.50.*

This is A Scientific Book Club Selection, and may well be read in connection with *Biological Basis of Human Nature*, by Jennings. The two are similar in field and in treatment. In this book the ability of environment, especially prenatal, to modify what might be considered as normal development and thus alter in various ways different individuals of identical genetic heritage, is emphasized. It is the outcome of the series of Lane Medical Lectures given

by the author at Stanford University, in 1930, rewritten and rearranged, however, in order to adapt it to the more general reader.

The author has succeeded in this object as far as is possible. It is useless, however, to claim that the material in Chapters III and IV, for example, is easily understood unless one has had some groundwork in biology. The matters discussed have puzzled physiologists and psychologists, and there is not even now agreement on some important points.

The known facts are here clearly given and a recognition of them would avoid the errors indulged in by many who consider themselves trained scientists. The subjects of senility and rejuvenation are considered, and it is clearly shown that the sex gland rejuvenation idea is based on an entirely erroneous conception.

The author is a well known anatomist, and his statements carry the weight of authority. The volume can be commended to all interested in the subject, and perforce all must be whether they recognize it or not. The printing and make-up of the book are excellent, the illustrations abundant and good.

ALLEN E. STEARN

Noguchi—By Gustav Eckstein. New York: Harper, 1931. 418 pp. Price, \$5.00.

This account of Noguchi and his work is written by a man who, according to his own account, was a dentist, studied medicine, and taught physiology, though he confesses that he "learned not much," but later "learned prodigiously" from making friends with two rats.

The book shows vivid imagination, and the jacket displays something of the same characteristics. The writer puts what he has to say in an interesting and often fascinating way. The style may be described as a succession of superlatives in staccato. Our objec-

tion to books of this type is that, being written for laymen who do not know the facts and are not able to analyze the statements made, wrong impressions of medical history are given.

It is perfectly true that Noguchi had quite a remarkable career. He was an indefatigable worker, did experiments on a grand scale, and undertook the solution of most difficult problems. His reputation will rest chiefly on his having been the first to cultivate artificially the germ of syphilis, and to demonstrate that this germ could be found in the brain matter of those suffering from general paralysis of the insane. The accuracy of much of his other work is extremely doubtful, and some of it known to be positively erroneous. His alleged discovery concerning the germ of yellow fever has been proved to be entirely wrong, and one cannot but regret that a man who had done so much that was good should have come to the end of his life under the shadow of such a mistake. It was a tragedy.

He overcame in a remarkable way the injury to his hand by a burn and his sensitiveness to the resulting deformity. It came near to causing his exclusion from the United States. The late Dr. J. J. Kinyoun of the U. S. Public Health Service was quarantine officer when he arrived, and hesitated a long time on this account before admitting him to the country.

The book is beautifully printed and illustrated.

M. P. RAVENEL

Silicosis. Records of the International Congress Held at Johannesburg, 13-27 August, 1930—By The International Labour Office: Studies and Reports, Series F. (Industrial Hygiene) No. 13, Geneva, 1930. (World Peace Foundation, 40 Mt. Vernon St., Boston) 694 pp. + 40 pp. of plates. Price (paper), \$1.00.

This is a report of a congress of some

50 world experts on silicosis, about half of whom were listed as members, representing Australia, Canada, Germany, Great Britain, Italy, Netherlands, Union of South Africa, and the United States of America. The balance were designated as observers who were from South Africa and also took an active part.

While the International Labour Office has followed closely the developments in silicosis throughout the world it was especially at the suggestion of Dr. Orenstein and the invitation of South African authorities, both official and industrial, that the congress was called. Dr. G. L. Ervine (Chairman of the Miners' Phthisis Medical Bureau, Johannesburg) was elected chairman of the conference and Prof. G. Loriga, Italy, and Sir Spencer Lister, England, vice-chairmen. There were 13 sittings held during the conference, the reports of which comprise 103 pages of the report. These include the chairman's address by Dr. Ervine and oral and written discussions upon the subjects of occupational conditions and methods of dust prevention, preventive measures, etiology and pathology of silicosis, its diagnosis as an occupational disease, statistics, and a draft report on preventive measures and compensation. The familiar name of A. Mavrogordato occurs frequently in the hearings, but we miss that of Haldane, who, however, was in South Africa the year before at another conference on the same subject.

The balance of the report contains some 20 major papers presented by experts in Johannesburg, and 14 special papers by the representatives of the various other countries named. These papers deal with practically all phases of the subject from historical aspects to sanatorium treatment, compensation, and actuarial valuation. Many tables, diagrams, bibliographies, and numerous half-tones accompany. There is no index but a brief table of contents and a list of members and observers are given,

as well as a verbatim copy of the entire transactions.

On page 562, Dr. Russell, of the U. S. Public Health Service, presents an interesting table of the industrial uses of silica and the types of silica used. An appendix on asbestos dusts is given by Dr. L. A. Garden and Dr. Donald E. Cummings of Saranac Lake.

The volume may well be considered as containing the last word in the world's knowledge of silicosis. It is printed in large type, very well edited and invaluable to those interested. It should dispose of the doubts which seem to exist in this country of the existence of silicosis as a disease entity and of the ability to compensate it fairly in view of the fact that the South African Bureau is now expending about a million pounds per year on the compensation features.

EMERY R. HAYHURST

William Henry Welch at Eighty—
Edited by Victor O. Freeburg. Published for the Committee on the Celebration of the Eightieth Birthday of Doctor William Henry Welch by the Milbank Memorial Fund, New York, 1930. 230 pp., 14 pl.

For his fine courage and rare ability to pursue truth into its innermost fastness, his broad vision of scientific conquests for the practical benefit of humanity, his warm zeal for discovering and developing the strength of others crusading for health, his charming genius for friendship, and his modesty, marked as his greatness, Dr. William Henry Welch has long been the recipient of cumulating honors and felicitations. When he reached the age of 80, on April 8, 1930, it was but natural that the legions of his followers, colleagues, personal friends and admirers should pay their tributes more abundantly than ever before.

A selected group of the most distinguished men in science, literature, statesmanship and the affairs of business and

philanthropy arranged the celebration for Dr. Welch's 80th birthday. Exercises to commemorate the event were world-wide. At Washington the speakers were President Hoover, Livingston Farrand, Simon Flexner and John A. Kingsbury. The book contains their tributes as well as Dr. Welch's charming and impersonal reply. In addition to the ceremonies at Washington, like gatherings were held simultaneously at the New York Academy of Medicine, the London School of Hygiene and Tropical Medicine, the Pasteur Institute at Paris, the Peiping Union Medical College at Peiping, China, the Kitasato Institute at Tokyo, Japan, and many other centers of medical education. Accounts of these observances are also included.

Theobald Smith says that the attempt to describe in a few words the place which belongs to Dr. Welch must necessarily degenerate into gesture (page 46).

The frontispiece of Dr. Welch, a reproduction of an etching by Alfred Hutty, is both a speaking likeness and a distinguished work of art. The book is admirably printed, exceptionally well edited and has a good index.

M. J. ROSENAU

The Prevention of Disease in the Community—By *Curtis M. Hilliard*. New York: McGraw-Hill, 1931. 193 pp. Price, \$1.75.

This small handbook is intended to give students a general idea of what is meant by public health. Students hear a great deal about personal health but often very little about health as it concerns a community as a whole or groups of persons in the community. This book is well adapted to give such general information. It is based on the scientific knowledge of disease and the most generally accepted methods for disease control.

It would probably have been more valuable if there were more references

to the sources from which information was drawn and a short bibliography outlined for those who might wish to get a more extended knowledge of the subjects treated.

The text has not been carefully edited, as there are a number of examples of inexactness of expression and of omissions. The table on page 159 does not state that the figures are per 100,000 population; on page 168 a table is called a diagram. It is barely correct to call toadstools (page 118) a food, or to suggest, as on page 120, that "such infectious origins should be discovered and condemned before the products can be used for food." They should be condemned to prevent their being used as food. Again, it is not fair to leave the impression, as on page 177, that the U. S. Public Health Service has been the only or always the main agency in getting the over 500 county health departments established in the United States. In some states this has been done by the state itself and in some counties by the county itself, in others by some of the agencies mentioned on page 188 or by other agencies. The U. S. Public Health Service has been, and at present is, especially active in stimulating states and counties to adopt the plan, but that Service is far from claiming the credit for all that has been done along that line.

There are a few places where the form of expression could be improved, as on pages 14 and 71, but outside of a few minor defects, easily corrected, the book is an interesting and instructive presentation of the subject.

JAMES WALLACE

Report of the Westchester County Sanitary Sewer Commission—November 20, 1929, to December 31, 1930.

Several records are claimed in the 1930 report of the Westchester County Sanitary Sewer Commission. One of these is the longest submarine sewer out-

fall, which is 2.42 miles long, 54" in diameter, and discharges into 51' of salt water on the Mamaroneck Valley project. Another is the longest sewer tunnel, extending over 5 miles under Mount Vernon and conveying sewage from Hutchinson Valley to the Hudson River. Still another is the largest self-contained sewage sterilization plant under one roof. This is the joint sewage treatment plant at Yonkers, where the following process is in effect:

1. Preliminary sedimentation with coarse screening
2. Fine screening with dewatering and incineration
3. Effluent disinfection with chlorine under laboratory control
4. Remote submarine discharge with deep salt water dilution

By the coming summer all pollution will be eliminated from the shore of Long Island Sound in Westchester County and the first steps taken to eliminate similar pollution of the Hudson, at Yonkers.

At the close of 1930 appropriations of \$23,670,925 had been received. A little over half has been spent. The largest single contract was for \$985,000 for the North Yonkers Tunnel. Much work had to be done by divers, and quicksand offered serious obstacles.

L. M. FISHER

Der Mensch. Vom Werden, Wesen und Wirken des menschlichen Organismus. *Herausgegeben vom Deutschen Hygiene-Museum, Schriftleitung: Dr. med. Martin Vogel, Wissenschaftlicher Direktor. Leipzig: Johann Ambrosius Barth, 1930.* 420 pp. Price, 47 marks.

One of the most interesting developments in the public health movement in Europe was the International Hygiene Exposition held last year in Dresden. It resulted in the permanent establishment of the Hygiene Museum. A book has recently been published which em-

bodies and illustrates much of the material which is on exhibition in the museum. There are 65 colored plates and over 300 other beautiful illustrations.

The first part of the volume deals with the structure of the cells and the tissues of the human body and with the functioning of the different organs. The second part sketches briefly the history of life upon the earth and traces the development of man from prehistoric times. The book is not a textbook but is written in a simple manner, utilizing the collections of the museum to arouse the interest of people and to teach them the important facts which they should know about the anatomy and physiology of their bodies. One of the most useful purposes of the book, however, is to bring to those of us who were not fortunate enough to visit the Dresden exposition an idea of what was accomplished there. It is a book that should prove of value to all public health workers.

DR. FELIX TIETZE, VIENNA

Proceedings of Eighth Annual Short School, Texas Association of Sanitarians, Amarillo, Texas, August 26, 27, 28, 1930.

The proceedings of this year's Texas Association of Sanitarians is divided into 5 major parts—waste disposal, water supplies, milk sanitation, epidemiological and laboratory studies, and miscellaneous public health problems.

In the waste disposal section a number of papers on garbage, refuse and trash collection and disposal are included. Sewage as related to irrigation is also touched upon.

Laboratory control of water supplies and the operation of swimming pools are subjects of two principal papers in the section on water supplies.

The important question of milk sanitation receives the attention of a number of writers who cover the operation of the standard milk ordinance in Okla-

homa, chemical sterilization of dairy equipment, and utensils, certain milk tests and discussions of certified milk, and dairy barn and milk house construction.

The remaining two sections of the transactions cover a miscellaneous group of papers, some of which refer to epidemiological investigations and others to health education, nursing, mosquito eradication and rodent control.

ARTHUR P. MILLER

Handbook of Protozoölogy—By R. R. Kudo. Springfield: C. C. Thomas, 1931. 451 pp., 175 ills., 1463 figs. Price, \$5.50.

This handbook differs from others in its field in being primarily a systematic résumé of this large group of animals. It is also characterized by its wealth of illustrations of representative, significant, and interesting species. The illustrations, though of necessity simplified, are uniformly of excellent quality both in the technic of drawing and in the quality of the reproduction and printing. Magnifications are always given and related forms grouped for comparison. This wealth of illustration and the wide range of material included give to Dr. Kudo's book a uniquely useful place both for laboratory instruction and as a work of reference.

C. A. KOFOID

Jamaica Health Stories and Plays—By B. E. Washburn, M.A., M.D., Rockefeller Foundation. Printed and Published by the Government Printing Office, 1929. 110 pp. Price, \$1.00.

This is a collection of health stories and plays, the former printed in the *Jamaica Public Health* through several

years; the latter given in the schools of the colony during the year of 1927-1928. While local interest is chiefly kept in mind and the material is, therefore, specifically applicable to meeting demands in Jamaica, the book offers much of value to any instructor who aims to arouse a live attitude toward disease prevention and personal hygiene among students of younger age.

LENNA L. MEANES

Elements of Water Bacteriology with Special Reference to Sanitary Water Analysis—By Samuel C. Prescott and Charles-Edward A. Winslow. (5th ed., rev.) New York: Wiley, 1931. 219 pp. Price, \$2.50.

This book, which has now reached its fifth edition, has been a laboratory essential for more than 20 years. This new edition maintains the standards set by the preceding ones, and doubtless the work will continue to hold the position so deservedly won.

The chief changes are to be found in Chapter V, which is devoted to the colon group, its classification and methods of isolation. We wish a fuller discussion of the Dominick-Lauter medium had been given. The method described by Dr. A. J. Salle, which had not been published when the manuscript was prepared, has been accepted at its face value, though the text gives no evidence that it has undergone the criticism of other workers. According to the authors, it "appears to show a marked superiority" over that given in *Standard Methods* of the American Public Health Association.

The printing and make-up of the book are excellent. M. P. RAVENEL

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Tennessee—The biennial report of the State Department of Public Health for the period ending June 30, 1929, occupies 154 pages of carefully prepared information, well printed. Infant mortality rates of 72.2 and 77.6 are noted for the years 1927 and 1928. An outbreak of influenza at the close of 1928 was the only important epidemic for the biennium. The number of cases and deaths from typhoid showed a notable decrease, as did most of the other communicable diseases. Tuberculosis remains an important problem, with a rate of 134. An annual per capita expenditure of \$.103 by the Department of Health in 1928 is compared with an average for 12 southern states of \$.136. Special efforts are described to secure the coördination of administrative affairs and the development of new programs and proper relationships with other agencies, including the medical profession.

Through the Division of Administration, a study is routinely made of the relationship of all new work to the program as a whole. Periodic studies are made as to the effectiveness of the various health projects of the department. Through conference and current reports, duplication of effort on the one hand, and program gaps on the other, have been avoided.

Success continues in the development of local health service.

Being entirely in line with the principles of democratic government which demand local responsibility and privilege, the county and city health departments have increased in efficiency and a greater number of citizens are each year being brought under the influence of reasonably adequate local health service. . . . In general, then, it may be said that the provision of local health service has proved itself sound and the outlook for continued and wider service is especially good in those counties containing at least \$10,000,000 assessed

valuation. In the smaller and not so wealthy counties, the problem remains difficult of solution. For instance, in a county with only some 3½ millions of taxable wealth, a tax rate of a little more than \$14 on the \$100 would be necessary to produce one-half of a minimum budget. As most of such counties are already struggling under relatively high tax rates, their ability to increase the county's income in order to provide for health service is definitely limited. To meet this situation, temporarily, the department has tried two plans: (1) Furnishing service only along special lines, as sanitation, public health nursing; and (2) by combining two or more counties into health department districts.

The report is well illustrated with excellent graphs, photographs and statistical tables. The general objective of the state health education program is to carry to the people of the state, both directly and indirectly, understandable information as to the fundamentals of health protection and disease control so that this knowledge may become usable as an integral, habitual part of daily life; and further to give sound information on public health problems and procedure, to the end that each county may provide its citizens with adequate health service. The program includes teacher training, health lectures in classrooms, classes in home hygiene, a public information service, personnel training, and consultant service.

New Brunswick, Canada—The construction of a new laboratory in conjunction with the new general hospital of Saint John is one of the outstanding events of the year, mentioned in the 1930 report of the Chief Medical Officer to the Minister of Health. Active immunization campaigns have been conducted in various districts resulting in the protection of some 35,000 children under the auspices of the Department of Health.

Efforts of travelling clinics are credited with much of the success in reducing tuberculosis mortality in the area to 84. Besides the diagnostic work associated with these clinics, efforts have been made to further health instruction. Over 54,300 school children were also given medical examinations and some 10,000 were vaccinated against smallpox. "Smallpox continues practically not to exist with us."

A birth rate of 24.4 and a general death rate of 12.5 are recorded.

Hawaii—The Territory of Hawaii, with a 1930 population of 370,620, records in the annual report of the Board of Health a birth rate of 29.6 and a death rate of 10.8. The infant mortality was 87.4 as compared with 101.7 in 1929, decrease for all races being noted except among the Portuguese and Hawaiians.

The control of tuberculosis is recognized as a health problem of first importance. Hence the director devoted considerable time to educational activities. A pamphlet, *What You Should Know About Tuberculosis*, was published in English, Japanese, and Filipino languages and widely distributed. The focus of publicity through the press was turned upon childhood tuberculosis. A new film was shown in the schools and before parent-teacher groups. Pamphlets and posters in schools, libraries, the Y. W. C. A., and in street cars were utilized. Special courses and lectures were given to nurses, physicians, and lay groups. On July 1, 1930, there were 2,325 active cases on the register, while 392 deaths occurred during the year, a decrease of 15 over the previous year. The problem is carefully analyzed in the report. A school survey was undertaken with the aid of funds from the American Association of University Women, in cooperation with the Boards of Education and Health. This work included tuberculin tests and X-ray examinations

(1,189). Through the coöperation of official and voluntary agencies, a preventorium was opened.

In the public health nursing field, generalized nursing was adopted in Honolulu through the pooling of nurses of the Board of Health and Palama Settlement; additional nurses, including supervisors, were added; prenatal clinics were opened on the island of Kauai, and improvements were made in the methods of health examination of school children. This is an excellent report of progress containing many valuable statistical tables, charts and photographs, with interesting descriptive text.

Newton, Mass.—In the 1930 report, a death rate of 8.3, the lowest in history, is recorded. This figure is based on a population of 65,763. A classified financial statement indicates an expenditure by the Health Department of \$.57 per capita. There were only 3 cases of diphtheria reported, with no deaths. Immunization work was continued. There were 80 cases of scarlet fever reported, with no deaths. The difficulty of detecting mild cases in the early stages of this disease is emphasized.

Physical examinations of school children revealed 5.7 per cent in all public schools to have physical defects as compared with 9 per cent among junior high school pupils. An infant mortality rate of 29.9 for the year is noteworthy.

Arizona—In 1930, through the aid of funds from the U. S. Public Health Service, a state-wide immunization campaign was organized which resulted in 38,904 diphtheria immunizations, 16,443 smallpox vaccinations, and 12,307 typhoid inoculations. Six schools were immunized 100 per cent against three diseases, and several others to the extent of 98 per cent.

During the year, the new State Building was completed, in which quarters were provided for the State Board of

Health on the first floor. A coöperative laboratory unit was established with the city of Phoenix and Maricopa County and the State Dairy Commissioner. In November the State Board of Health maintained an exhibit booth at the State Fair in collaboration with the State Medical Association. Approximately 50,000 pieces of health literature were distributed during the week.

Commonwealth Fund—New developments in the field of public health, with effort particularly devoted to the building up of better health service for rural communities, are described in the twelfth annual report of the Commonwealth Fund. Coöperative arrangements have been established during the year with the state health departments of Tennessee and Massachusetts whereby in each of these states intensive work has been undertaken in two rural districts, and special provision has been made for the training of rural physicians. The selection of other states for similar coöperative effort is pending. According to the report:

It is the interplay between public health and the private practice of medicine that gives the new health program its distinctive character. The problem of the typical rural community is to make use, more deliberately and more wisely, of all the available resources for the promotion of health and the cure of disease. The rural physician has usually defended his patients single-handed against illness and premature death. He must always carry the major responsibility, but he need not stand alone, and if he can get a firm grasp of modern medical technique, he may be able to move forward from his defensive position and lead an aggressive attack on disease.

Under the program initiated by the Fund, the local health authorities in each of the selected rural districts will be aided to develop their service to the point of greatest usefulness within the limits of sound budgeting, on the understanding that all expenses, during the

introductory period, will be shared between the county, the state, and the Fund.

In each state, 15 scholarships will be provided annually for rural physicians, 5 in each of the special districts and 5 in the state at large. The medical school chiefly responsible for the training of rural physicians in each of these states will be helped to develop its teaching of preventive medicine and its facilities for postgraduate training. Scholarships or loan funds will be provided for undergraduate students of medicine who agree to go into rural practice. Scholarships for postgraduate nursing study will also be offered.

The new program follows and supplements work which the Fund has been doing for some years in the field of child health and in the establishment of rural hospitals, 6 of which have now been built through the assistance rendered to various communities. In fact, the plan for scholarships whereby local practitioners might return to medical schools for postgraduate work was started in connection with the rural hospital program, and from the 6 communities, 82 local physicians have been given the opportunity for such study.

The appropriations made by the Fund during the year totalled \$2,095,-918, covering a wide range of activities mainly in the fields of public health, mental hygiene, and British-American relations. In the field of mental hygiene, the report covers the first year's work of the Child Guidance Clinic, established in London in accordance with plans formulated by the Child Guidance Council. The Council, organized by the Fund, serves the whole of Great Britain; it gives advisory service to those interested in forming new child guidance clinics and coöperates with the London School of Economics and Political Science in its training school for social workers.

Continued support has been given to

the Institute for Child Guidance established by the Fund in New York primarily to meet the great need for a larger number of well trained personnel in this field.

The efforts of the Legal Research Committee have continued to center upon projects in administrative law, including studies of the Interstate Commerce Commission, workmen's compensation laws, and the administrative

powers and methods of the Department of Agriculture. Another study made under the direction of the University of Chicago Law School and dealing with insanity as a defense in criminal law, is approaching completion. Special grants were given to 41 outside organizations, hospitals and universities for various projects. These included many research undertakings in the field of preventive medicine.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Diphtheria Mortality Rates—The annual tabulation of diphtheria death rates for large cities reveals the lowest rate ever recorded, about half that of 5 years ago. Whether this is due to the general use of toxoid and toxin-antitoxin or to a decrease in general susceptibility remains to be proved. But the figures encourage the extension of the prophylactic program.

ANON. Diphtheria Mortality in Large Cities of the United States in 1930. *J. A. M. A.*, 96, 21: 1768 (May 23), 1931.

Typhoid Fever Mortality—The annual compilation of typhoid fever mortality rates for the large cities of the country in 1930 shows the usual interesting statistics. The rate for the entire country is the same as that for 1929.

ANON. Typhoid in the Large Cities in the United States in 1930. *J. A. M. A.*, 96, 19: 1576 (May 9), 1931.

Physical Defects and Sex—Rates of physical impairment are higher for women than for men, notably so in respect to thyroid conditions, visceroptosis, edema, adenitis, varicosities, heart conditions, tuberculosis, etc. The rates for men were greater in the case of urine casts, defected septum and arterial thickening.

BRITTEN, R. H. Sex Differences in the Physical Impairments of Adult Life. A Comparison of Rates among Men and Women Based on 112,618 Medical Examinations by the Life Extension Institute. *Am. J. Hyg.*, 13, 3: 741 (May), 1931.

About Leprosy—A non-technical discussion of leprosy and control measures.

FORD, W. W. Leprosy in the United States. *Sci. Monthly*, 32, 6: 513 (June), 1931.

Weather and Colds—Evidence is presented which suggests that changes in weather during a warm season are probably associated more closely with common cold incidence than weather changes during the season of low temperature.

GAFATER, W. M. Upper Respiratory Disease (Common Cold) and the Weather. Baltimore, 1928-1930. *Am. J. Hyg.*, 13, 3: 771 (May), 1931.

Bacterial Content of Dry Milk—About 200 samples of dried milk preparations used in infant feeding were tested. The total bacteria count varied from 1,000 to 10,000 bacteria per gm., but no pathogenic streptococci or tuberculosis bacilli were present.

GIBLIN, J., and VON POURTALES, J. H. Dried Powdered Milk Preparations Used in the Feeding of Infants. *Am. J. Dis. Child.*, 41, 5: 1100 (May), 1931.

Preschool Health Education—How constructive are health songs, plays and pageants? This paper answers the question so far as preschool ages are concerned.

HARLEY, W. Health Education for Preschool Children. *Pub. Health Nurse*, 23, 5: 213 (May), 1931.

Urinalyses and Health—The limitations of the urinalysis as a health index as well as its place in health diagnosis are both covered in this brief paper.

KILDUFFE, R. A. Urinalysis as an Index of Health. *Am. J. Nurs.*, 31, 5: 563 (May), 1931.

The Laborer is Worthy of His Hire—Physicians in public health receive the lowest average income of any in a salary survey of a large medical

group. However, the health official's salary, which is net, is compared with the gross income of private practitioners the median of which is \$6,500-\$7,500.

LELAND, R. G. Income from Medical Practice. J. A. M. A., 96, 20: 1683 (May 16), 1931.

Progress in Public Hygiene—The events of the year 1930 are reviewed briefly; the fields covered are public health measures, private and clinic practice, legal measures, awards, and research. A most useful reference paper.

MOORE, H. H. Progress during 1930 in Medicine and Public Health. New England J. Med., 204, 19: 994 (May 7), 1931.

A City's Health Progress—Originally surveyed in 1923, resurveyed twice since to establish progress along lines laid down, Knoxville was given another going over to estimate achievement as originally projected and to help arrive at a continuing program. A record for periodic health examinations, it would seem.

MOUNTIN, J. W. Public Health Progress in Knoxville, Tenn. Pub. Health Rep., 46, 20: 1150 (May 15), 1931.

Septic Sore Throat Outbreak—An explosive outbreak of septic sore throat causing 450 cases with 4 deaths in Canada is reported. Infected raw milk was the avenue of spread, the suggestive evidence indicating a cow's udder infected by human carriers.

McKAY, A. L., *et al.* A Septic Sore Throat Epidemic. Canad. Pub. H. J., 22, 5: 224 (May), 1931.

County Health Administration—That the appraisal form, as applied to one Tennessee county, helps to maintain a balanced program is the opinion of this health officer.

ROBERTS, F. L. Criteria for Maintaining Balance of Program in County Health Departments. Pub. Health Rep., 46, 19: 1079 (May 8), 1931.

Toys for Toddlers—Ask of each toy: what can the child do or make with it? Is it suited to the preschool age? Good toys are fraught with the highest educational possibilities.

ROBINSON, M. H. Educational Play Materials for the Preschool Child. Pub. Health Nurse, 23, 5: 219 (May), 1931.

Chance of Brucella Abortus Infection—In Denmark 272 persons working with cattle were tested for *Br. abortus*; 94 per cent of a group of veterinarians in rural practice reacted positively. Other groups responded in proportion to the exposure to sick cattle. Milk had no proved connection with the reactions.

THOMSEN, A. Correlation of Occupation with Serologic Reactions for *Brucella abortus*. J. Infect. Dis., 48, 5: 484 (May), 1931.

More About Scarlet Fever—This Japanese study of the etiology of scarlet fever confirms American opinion of the rôle played by the scarlatinal streptococcus.

TOYODA, T., *et al.* Scarlet Fever. Am. J. Dis. Child., 41, 5: 1009 (May), 1931.

Use and Danger of Fumigants—How to use hydrocyanic acid and how to avoid the dangers incident to fumigation with this substance are clearly set forth in this paper.

WILLIAMS, C. L. Fumigants. Pub. Health Rep., 46, 18: 1013 (May 1), 1931.

Tuberculosis Case-Finding—Reviewing the 7-year record of the Chadwick clinics in Massachusetts, the author concludes that nothing really new has been learned, but what is shown (and most graphically, too) is that a comprehensive control program is badly needed if youth is to be saved from tuberculosis. A paper all should read and ponder over.

ZACKS, D. What We Have Learned from the Ten-Year Program in Massachusetts. New England J. Med., 204, 20: 1037 (May 14), 1931.

NEWS FROM THE FIELD

NEW SURGEON GENERAL FOR U. S. ARMY

DR. ROBERT U. PATTERSON has been appointed Surgeon General of the United States Army by President Hoover, with the rank of Major General, succeeding Dr. Merritte W. Ireland.

SICKNESS AMONG INDUSTRIAL EMPLOYEES

ACCORDING to the U. S. Public Health Service, a favorable health record among industrial workers during the second half of 1930 is indicated from reports of a group of industrial sick benefit associations covering about 135,000 male industrial employees.

RESEARCH FUNDS

THE Elizabeth Thompson Science Fund of Harvard University and the Sugar Institute are the latest donors of research funds to Dr. Harry J. Deuel, Professor of Biochemistry in the School of Medicine, University of Southern California. Previously the National Research Council and the Committee on Scientific Research of the American Medical Association made grants to him.

The funds are being used by Dr. Deuel to further his research in the antiketogenic value of carbohydrates. He had for his purpose the determination of the power of various sugars to reduce acidosis produced in individuals by a uniformly protein-fat diet.

SOCIAL HYGIENE

THE Massachusetts Society for Social Hygiene announces a competition, with a prize of \$500, for a suitable manuscript on the subject of sex hygiene for adolescent boys and girls.

The contest will close October 1, 1931, and the prize will be awarded January 1, 1932. Further particulars may be obtained from the Massachusetts Society for Social Hygiene, 1150 Little Building, Boston, Mass.

AMERICAN COLLEGE OF PHYSICIANS

THE American College of Physicians will hold its Sixteenth Annual Clinical Session at San Francisco with headquarters at the Palace Hotel, April 4-8, 1932. Following the Clinical Session, a large percentage of the attendants will proceed to Los Angeles where a program principally of entertainment will be furnished April 9, 10 and 11.

E. R. Loveland, Executive Secretary, 133-135 S. 36th Street, Philadelphia, Pa., is in charge of general and business arrangements, and may be addressed concerning any feature of the forthcoming Session.

ADVANCEMENT OF SCIENCE CENTENARY

THE British Association for the Advancement of Science will celebrate its centenary with a meeting in London, September 23-30, 1931. Particulars may be obtained on application to the Secretary, British Association, Burlington House, London, W.I.

NEW CRIPPLED CHILDREN'S HOSPITAL

A NEW \$300,000 Wisconsin Orthopedic Hospital at Madison, Wis., is to be opened early this summer, according to a report from Wisconsin. It will have a solarium, open sun porch, playroom, and rooms for occupational therapy. One of the most sensible ideas carried out in this hospital is the reservation of the ground floor for patients who are able to get out of doors.

The building has a capacity of 113 beds, which will make hospital care available to many crippled children for whom facilities heretofore have been lacking.—U. S. Children's Bureau, Washington, D. C.

TEXAS SANITARIANS TO MEET

THE Ninth Texas Sanitarians' Short School will be held at Houston, with headquarters at the Rice Hotel, November 9-14, 1931, under the auspices of the Texas Public Health Association, with the Texas State Department of Health and the City of Houston co-operating.

The Short School will be conducted as two sessions this year, Laboratory and General, intended to embrace the general phases of public health activities such as nursing and welfare, food protection, laboratory control, and milk sanitation. Special attention is expected to be devoted to those attendants desiring instruction in laboratory work either for milk, sewage or water analysis.

AUXILIARY WATER SUPPLIES IN DROUGHT AREA

THE 1930 Annual Report of the Division of Sanitation of the State of New York brings out the striking fact that although many communities were obliged to resort to polluted auxiliary water supplies during the drought last year, not a single outbreak of water-borne disease resulted from their use. This was doubtless due to the prompt reporting by communities of intention to use auxiliary supplies and the installation by the division of emergency apparatus for the sterilization of the water. The work of supervising public water supplies increased considerably, owing to the drought and a total of 579 inspections was made, over 150 more than in 1929.—*Health News*, May 11, 1931, New York State Dept. of Health, Albany, N. Y.

CONNECTICUT CHILD-WELFARE COMMISSION

A NEW child-welfare commission has been recently appointed in Connecticut to study the child welfare progress made in the state since the recommendations of the commission of 1921 brought about sweeping changes in methods of child care. These resulted in the establishment of the bureau of child welfare, the juvenile court, and the department of special education in the public schools. The new commission, which serves without compensation, has been requested to present its report, including legislative recommendations, to the legislature convening in January, 1933.—U. S. Children's Bureau, Washington, D. C.

HEALTH FILMS BY TELEVISION

THE first known attempt in history to send health films by television was made by the New York State Department of Health over station W2XCD, Passaic, N. J., March 30, 1931.

PENNSYLVANIA SEWAGE ASSOCIATION CONFERENCE

THE Fifth Annual Conference of the Pennsylvania Sewage Association was held at State College, Pa., June 23 and 24. Among the speakers were: Frank E. Daniels, Harrisburg; Harry Krum, Allentown; Albert H. Mainwaring, Philadelphia; Roy L. Phillips, Meadville; C. F. Wertz, Philadelphia; Grant M. Olewieler, Montgomery County; Elton D. Walker, State College; F. S. Barckhoff, Salem, O.; John R. Downes, Plainfield, N. J.; and H. W. Streeter, Cincinnati, O.

THE HEALTH EDUCATION COUNCIL CONFERENCE

THE sixth annual conference of the Health Education Council was held at the Massachusetts Institute of Technology on June 5 and 6.

Dr. S. C. Prescott, head of the department of biology and public health at Massachusetts Institute of Technology, delivered the address of welcome at the opening session. In connection with the meeting there was a comprehensive health education exhibit.

The officers of the Health Education Council are: Clair E. Turner, honorary president; Ida M. Lewis, president, Brookline; Mabel E. Turner, vice-president, Lowell; and Adelaide R. Ross, secretary-treasurer, Malden.

RUSSELL SAGE FOUNDATION

JOHN M. GLENN, general director of the Russell Sage Foundation since its inception 24 years ago, has resigned that post, but will continue to serve as one of the trustees of the Foundation. Shelby M. Harrison, director of the Department of Surveys and Exhibits of the Russell Sage Foundation since 1912 and

vice-general director in recent years, will succeed Mr. Glenn as general director on September 1, 1931.

While not primarily interested in public health the Foundation under Mr. Glenn's leadership has frequently concerned itself with the health aspects of social problems. The early educational efforts of the tuberculosis movement were largely made possible by the Foundation. Movements have been fostered or studies made in such fields as the prevention of blindness, industrial accidents, work fatigue, housing conditions.

Mr. Harrison has been with the Foundation for 19 years, as director of the Department of Surveys and Exhibits, and for several years as vice-general director has been closely associated with its general management.

No change in Foundation policies is expected.

PERSONALS

FLOYD C. MILLER, of Athens, Greene County, N. Y., has been appointed a member of the Advisory Committee on Milk Sanitation of the State Department of Health.

WILLIAM L. KELLER, M.D., Colonel, Medical Corps, chief of surgical service, Walter Reed General Hospital, Washington, D. C., was the recipient of the honorary degree of Doctor of Science at the commencement exercises of the Medical College of Virginia, Richmond, closing the ninety-third session of the institution on June 2.

DR. MORTON W. BLAND, Health Commissioner of Logan and Hocking Counties, O., died April 21, at the Harding Rural Rest Home, Worthington, O.

DR. HENRY FAIRCHILD OSBORN, who on January 1, 1933, will conclude 25 years as president of the American

Museum of Natural History, New York, will relinquish his duties at that time. This was made known in the 62d annual report of the president and trustees of the museum.

RICHARD A. BOLT, M.D., Director of the Cleveland Child Health Association, will spend the summer in California. From June 22 to August 1 he is giving two courses in the summer session of the University of California at Los Angeles. One of the courses will take up elementary epidemiology and the other will deal with the field of public health in the United States.

HERMAN N. BUNDESEN, M.D., Fellow of the A. P. H. A., and President in 1928, has again been appointed to the position of Commissioner of Health of Chicago, which he held from February, 1922, to January, 1928. He has recently been Coroner for Chicago.

ENNION G. WILLIAMS, M.D., Virginia State Health Commissioner since 1908, died June 6. He was the oldest state health officer in length of service in the United States, though only 57 years of age. Dr. Williams was a member of the faculty of the Medical College of Virginia. He has been a member of the A. P. H. A. since 1905.

CONFERENCES

July 26-31, Third Congress of the Pan American Medical Association, held under the auspices of the Mexican Government, City of Mexico, Mexico.

July 27-August 2, The World Federation of Education Associations, Denver, Colo.

September 14-17, Sixtieth Annual Meeting, American Public Health Association, Montreal, Canada.

September 23-30, Centenary Meeting of the British Association for the Advancement of Science, London.

October 12-16, Nineteenth Annual Safety Congress and Exposition, Chicago, Ill.

November 9-14, the Ninth Texas Sanitarians' Short School, Houston, Tex.

July, 1932, The Second International Conference of Social Work, Frankfurt, Germany.

The Infant Before, During, and After Birth*

RICHARD ARTHUR BOLT, M. D., DR. P. H., F. A. P. H. A.

Director, Cleveland Child Health Association, Cleveland, O.

OUR present knowledge of the principles of child hygiene and the varied experience gained through their practical application to local communities during a quarter of a century, place us in a position to evaluate present trends and consider future developments. It is comparatively simple to outline a broad program for child hygiene. It is, however, quite another matter to fit such a program to the diverse needs of various types of localities, to secure adequate funds for financing measures deemed necessary, and to conduct a local organization over a sufficient period to demonstrate that our program is sound and effective.

The development of a consistent and progressive child health program over a long series of years has been carried out in so few places that it is difficult to assess with any assurance the relative values of different methods employed. Most of our efforts in this field have been either spasmodically intensive or conservatively prolonged. Progress has been made, of course, by the application of certain fundamental principles, notably in the field of infant hygiene, though much still remains to be done in the maternal, neonatal, and preschool areas.

We have been led to believe, through high powered publicity, that great strides have been made in our child hygiene work. This is undoubtedly true when applied to the care of the baby. In our prenatal program, however, and in the prevention of maternal and neonatal mortality, we have scarcely made an impression. Much progress has

* Read before the Child Hygiene Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

been made in scientific principles of infant feeding, prevention of nutritional diseases, protection of milk supplies, and technic of public health nursing. We begin to see the results of our antidiphtheria campaigns, and the protection of children against tuberculosis, but very little progress has been made in the control of whooping cough, measles, and the respiratory diseases.

The child health demonstrations which have been completed in centers throughout the country have brought us valuable data and indicate practical methods applicable to individual communities. It is essential now to show that similar methods can be applied with equal success to other places at costs which the communities can afford.

The United States as a whole reached its highest interest in maternal and infant hygiene during the years when the Sheppard-Towner Act was in force. Then it was possible to institute measures for the protection of mothers and babies in every state. A great impetus was given to child hygiene in the rural districts and small towns. Public health nursing was extended considerably. Since the expiration of the Sheppard-Towner Act it has been impossible to continue the work as extensively in a number of the states, especially in the South and West. The organization for child hygiene in some states has almost completely broken down. Much of the ground gained during the 7 years of Sheppard-Towner activity will be lost if means are not found soon to continue.

In other places, where child hygiene had been organized prior to the Sheppard-Towner Act, there is a tendency to consolidate the work and spread the general health program over the whole child hygiene field. While a great deal of interest is being expressed now as to the outcome of the White House Conference, there is no question that the child hygiene work in many communities has been retarded by withdrawal of state and federal assistance. A period of reaction has commenced which may seriously affect our whole child welfare program.

An interesting phenomenon in regard to infant mortality manifests itself in times of depression—the rates continue to fall during the period of unemployment and economic depression. This may be due to a number of factors. The impetus given infant hygiene by the prosperous years may continue. Widespread popular education in child hygiene is conducted despite the depression. Another factor, seldom stressed in connection with times of depression, is that mothers are forced to remain at home with their babies and breast feeding is encouraged. The lot of the older children, however, is not so favorable, as it becomes more difficult to feed them properly and to afford adequate medical supervision.

Our objectives in the community child hygiene program appear to be changing gradually. From a program designed primarily to prevent infant mortality, we are developing interest in the survivors. The prevention of both morbidity and mortality in older children, as well as infants, demands our best efforts. Our interest has broadened to include the whole child and all age groups.

It is, therefore, quite appropriate to consider in this paper the conditions which affect the whole child before, during, and after birth. Child hygiene, while theoretically beginning with conception, has its background in the health of father and mother and the stocks from which they have sprung. We must always reckon with hereditary factors in any inclusive program for child welfare. At conception heredity is sealed. From then on environment will modify or mold the individual along patterns which heredity has laid down. It is futile to argue which has the more influence, heredity or environment. Both are integral parts of the whole individual and act and react, one upon the other.

From conception to birth the fetus is completely environed by its mother. For all practical purposes it is a parasite, supported and protected by her. It receives nourishment, oxygen, and heat through her and is dependent upon her for the removal of its wastes. No direct nervous connection between mother and fetus has ever been demonstrated. It is quite evident, therefore, that anything we do for the child before birth must be accomplished either through heredity before conception, by means of race hygiene, or through the medium of the mother, from conception until birth. While we do not possess all of the scientific knowledge necessary to afford complete protection to the developing embryo and fetus, we do have enough to prevent many of the disasters which still occur. The earlier the prospective mother is brought under skilled medical and nursing supervision, the more opportunity we have to afford adequate protection.

Any complete community program for the hygiene of the child must begin with pre-parental and parental instruction, especially of the mother. It might well begin by providing instruction for prospective mothers, including hygiene of pregnancy and infancy. To be most effective this education should begin in the junior and senior high schools as a part of the home economics courses. Where this instruction is combined with practical demonstration in a child welfare center or nursery school, it will net the greatest returns. One of the most important functions of the public health nurse is to provide the mother with direct and practical instruction, through the health center and in the homes. No amount of broadcasting of general information on

child hygiene can take the place of personal first-hand training in a definite situation.

The educational measures which could be used to advantage may be summarized as follows:

1. Mothercraft classes in public schools, with actual demonstrations in infant welfare centers and nursery schools
2. Prenatal group instruction at health centers or in obstetric outpatient departments
3. Prenatal education by monthly letters, pamphlets, and carefully edited press articles
4. Individual instruction by doctors and nurses in private practice, and in prenatal centers
5. Encouragement for mothers to go early to their physicians for prenatal examination and have regular follow-up by public health nurses

Some form of maternity benefit or savings is urgently needed in this country to meet the extra expenses incurred during pregnancy. This need not in any way interfere with routine medical practice, nor disturb the personal relationship between physician and patient. The experience of several life insurance companies in extending prenatal and postnatal nursing care to their industrial policy holders warrants a wider acceptance of the insurance principle applied to maternity care.

Revision of birth certificates and maternal mortality reports is desirable, that they may state clearly the circumstances before and during birth. It is impossible, with our present certificates, to trace many important facts relating to physicians or others in attendance upon the mother. No information is given regarding prenatal care nor definite indications of obstetric operations performed. More detailed study of stillbirths, neonatal deaths and maternal deaths should be made by local health authorities. Publication of standardized reports from maternity hospitals and maternity homes should be made obligatory and the data and nomenclature used by all should be sufficiently uniform to be comparable.

Notification of births within from 24 to 36 hours with a report on the condition of mothers and babies would aid materially in making possible suitable nursing follow-up. This has been done in England and Scotland for some time with excellent results. Every mother should have not only a skilled, judicious physician at the time of delivery, but also a capable trained nurse, who can give postnatal as well as prenatal care. An extra pair of trained hands at delivery would also afford greater protection to mother and babe.

One of the greatest problems today is abortion. Some way to limit the number of abortions must be found if the number of maternal deaths is to be reduced. Available statistics indicate that a number of such deaths follow abortion, usually induced. Educating women to the dangers of this practice is not enough. Unless we are courageous enough to handle the abortionist as a public menace, secure his prosecution, and exclude him from our medical associations, we will accomplish little. At present the professional abortionist wears sheep's clothing. He practises on the *élite* and the *hoi polloi* alike.

Public health authorities have a right to know under what conditions mothers are being delivered and the risks to which they are exposed. They have already acquired power to inspect, license, and supervise midwives, and there is no reason why they should not know the facts regarding confinement in maternity homes and lying-in hospitals. The relative safety of such institutions should be determined by investigation by the local health authorities. The results of such a study may profitably be taken up with the medical society, together with suggestions for improvements. A detailed investigation of every maternal death would also yield valuable information which should be of service to both the medical profession and health authorities.

The problem of suitable obstetric service in rural districts can be solved to a great extent by the provision of county or district hospitals with maternity service, and by the extension of public health nursing. If the medical profession cannot meet the pressing demands of rural districts and certain areas of the South, where the largest midwife practice now prevails, there seems to be no logical reason why we should not give additional training to our registered nurses and license them to care for normal obstetric cases. This is being done with great success in a number of foreign countries and by the Pioneer Nursing Service in the Kentucky mountains. Either the medical profession must meet this emergency, or it will be solved in some other way by the community.

It is evident that there has been a diminution of the child hygiene work since the Sheppard-Towner Act expired. The appropriation in some states has been definitely cut, while in others the work has been hampered through political motives. While theoretically each locality should look after its own maternity and child hygiene problems, this is practically impossible in small towns and wide stretches of country without state or federal assistance.

The greatest danger at present is that health departments may attempt to live on their reputation for sanitation and be content with reduction of infant mortality by "tried" methods, rather than extend

exploration to other fields and attempt to convince communities of the need for broader public health measures.

The condition of mother and child immediately after birth depends largely upon prenatal and intranatal conditions. Thorough care of the new-born as to feeding, prevention of infections, etc., is necessary. Breast feeding is very important, especially in the early weeks, and cannot be stressed too strongly. Follow-up in the homes by competent nurses, after mothers have left the hospital, is most important. This can be accomplished best and most reasonably by well trained public health nurses. As a matter of fact the public health nurse is really the key to child hygiene. As health educator, home visitor, follow-up worker, she is in a strategic position. It should be understood clearly that not only the prevention of mortality among mothers and babies interests us, but also the morbidity—the damage which they suffer as a result of childbirth. The prevention of ophthalmia neonatorum is an excellent illustration of what can be accomplished by central public health authority backed by reasonable laws.

The technics of infant care after 1 month of age and through the first year of life are fairly well defined. They consist essentially in periodic examination by the physician, careful direction of feeding and hygiene, and prevention of infection. These measures may be employed in infant welfare centers or by a private physician in his own office. In a number of large cities, from 50 to 70 per cent of the babies now reach the hands of physicians for preventive care.

While in theory it is admirable to "consider every physician's office a health center," in practice it is impossible to establish such an attitude on the part of many parents. Most physicians are not equipped to attract and handle a large number of babies in their private practice. Furthermore, parents of the lower and middle economic classes cannot afford such service for well babies. It is essentially a function of the local health authorities to provide for the examination and hygienic supervision of *well* babies. This is done best through infant welfare centers as a part of community health centers. It will always be possible to secure the services of young physicians, well trained in pediatrics, to attend such centers. These physicians should, of course, be paid for each clinic hour in attendance. The sick babies should be referred to private physicians, or to babies' dispensaries or hospitals when the parents cannot afford to pay. Experience has demonstrated that this type of service has increased rather than diminished preventive pediatrics in private practice.

At present a certain amount of lag in our infant welfare program is due to the reactionary tendency of some physicians to look upon the

health care of young children as their private prerogative and to discourage the growth of local health centers. As only the well-to-do and better-off of the middle class can really afford to pay for systematic care of well babies, it is in the interest of community welfare to see that careful examination and hygienic regimen are available for all babies, either at the hands of the family physician or in health centers.

While a great deal has been done to encourage vaccination and toxin-antitoxin immunization, more is required, especially in the first year of life. There is a tendency, even among some physicians, to defer vaccination and diphtheria immunization. These measures should be offered in infant welfare centers as part of the general preventive work, until private physicians make more adequate provisions for them.

While protection against measles by use of convalescent serum or adult blood has not been widely practised, in New York City and elsewhere it has been thoroughly demonstrated that it is practical for a local health department to collect such blood and make it available to practising physicians. Similar provisions should be made for the collection and preservation of immune poliomyelitis serum.

To sum up: The practical application of community child hygiene measures may be effected:

I. *For the Infant before Birth* by:

1. Parental and pre-parental education, carried on through the public schools and extension divisions of universities, and by the local health authorities
2. Encouraging expectant mothers to place themselves early in the care of a competent physician and nurse
3. Systematic follow-up on the part of public health nurses
4. Some practical means of savings or maternity benefit
5. Protection of mother against infectious diseases and provision of adequate nutrition
6. Freedom from industrial stresses and strains, especially during the latter months of pregnancy

II. *During Birth*—the safety of both mother and child is almost entirely in the hands of the physician and nurse and depends largely upon:

1. Better obstetric training for both physicians and nurses
2. Competent nursing before, during, and after birth
3. Hospitalization of obstetric cases under suitable safeguards
4. Discouraging of bizarre or hurried obstetric practice
5. More complete reports on maternal mortality, stillbirths, and neonatal deaths with a thorough investigation of each case

III. *After Birth*—the immediate results are largely in the hands of the physician and nurse, but depend upon good prenatal and obstetric care. There should be:

1. Prompt notification and registration of births
2. Follow-up of all births by public health nurses
3. Regular, systematic examination of all well babies, and supervision as to hygiene and preventive pediatrics
4. Prevention of communicable diseases by immunization where possible

Practical application of child hygiene depends upon preventive obstetrics and pediatrics, the organization of local health centers, and thorough follow-up by public health nurses.

Dental Decay and School Work

A STUDY of over 19,000 elementary school children was recently made in Magdeburg, Germany, for the purpose of ascertaining the relation between dental decay and poor school work. Only cases of decay of both the permanent and the milk teeth were considered. Of the 19,000 children nearly 1,200 were retarded.

It was found that dental decay as defined above was 11.5 per cent more frequent among the retarded children than among those who were regularly promoted. More than one-half of the retarded children with dental decay belonged to the poorer families, such as low paid clerks, laborers, and widows without means. Somewhat similar data were obtained in other studies. It was also found that 68 per cent of the retarded children in the present study had had rickets in their early childhood, while other investigations of school children in general showed a percentage of rickets varying from 21 to 45.

The investigator came to the conclusion that hygienic and economic conditions of the child's environment and also rickets are the cause of the higher rate of dental decay among the retarded children; also that extensive dental decay often impairs the child's nutrition and results in poor school work, and rachitic children are more likely to be thus affected than those free from rickets.—*Gesundheitsfürsorge für das Kindesalter*, Berlin, 6, 1: 1-28, 1931.

The Community Health Program as It Applies to the Child of from One to Six Years*

CHARLES F. WILINSKY, M. D., F. A. P. H. A.

Deputy Commissioner of Health, Boston, Mass.

COMMENDABLE, indeed, and in keeping with the progress of the day, is the increasing appreciation of the significance and importance of adequate programs for child health conservation. It has been well said that a community's child health program is an index of its intelligence. There is an increasing realization of the fact that the nation's greatest asset is the health of its children. This viewpoint is not a new one. It contrasts with the days of ancient Greece and Rome only because in those days it was frequently left to the judgment of the State whether a child might be permitted to live, whereas today our child health program gives evidence of the community's interest in the principle that every child has a right to be born well.

We know much about the prevention of disease and the promotion of health among the young and yet, unfortunately, necessary expenditures for the development of adequate programs for life extension in this group are not being provided. Many supposedly intelligent communities still exhibit an unmindfulness of Dr. Dublin's emphasis on our true wealth measured in terms of the earning power of our human resources. One would hesitate, and almost question the need of emphasizing the value and significance of child health programs to a group of public health workers, were it not for the absence of the same from many communities.

Dr. Bolt has presented his views on the infant before, during and after birth. His emphasis on the relative values of prenatal services, adequate care at childbirth and during the first year of life, is of exceeding importance to the well-being of the child of from 1 to 6 years of age. He has very properly stressed the significance and importance of periodic medical supervision during the first year of life. It is, of course, fitting at this time to make mention of the value and impor-

* Read before the Child Hygiene Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

tance of the continuance of this routine medical supervision for the child of from 1 to 6. It is perhaps pertinent to establish a minimum standard for such examinations of at least once every 6 months, if more frequent ones are impractical or impossible.

It is quite generally agreed that the preschool age child, of whom there are about 12 million in the United States, furnishes a most excellent opportunity for intensive health effort. Everyone charged with the responsibility for the development of community health service should exhibit a mindfulness of the possibilities that exist in this age group for future good health—physical, as well as mental. This has been aptly called the “plastic” age and, unfortunately from the viewpoint of general accomplishment, the neglected age. Mothers who have rather frequently brought their babies to child health clinics periodically appear to have presumed that after these youngsters have arrived at the age of 1 year there would be no further need for medical supervision, and have abruptly ceased to bring them to either doctor or clinic. It is this attitude by parents, in view of our knowledge and experience, that justifies the correct presumption that this is, indeed, the “neglected” age.

MORBIDITY AND MORTALITY IN THE PRESCHOOL AGE

The general susceptibility of this group to disease and its unpleasant results call for the exercise of all well known measures for the control of these conditions. We are fundamentally aware of the exposure and susceptibility of this group to communicable diseases, and this immediately suggests the importance of organization on a basis to assure a maximum of possible prevention, as well as control, both through the instrumentality of immunization as well as of isolation. We are informed that four-fifths of all of the deaths which occur from contagious diseases are in children under 5, and also that of all deaths in all age groups from all causes 25 per cent occur in children under 5. This is a challenge to the imaginations and consciences of all intelligent health officers and calls for a program for the prevention and control of these diseases among the young.

PHYSICAL DEFECTS FOUND IN PRESCHOOL CHILDREN

Examinations of preschool age youngsters upon entering school have revealed a high percentage of physical defects, among the most prevalent being defective teeth, enlarged or diseased tonsils and adenoids, defective breathing, defective vision, defective hearing, nervous defects, and undernourishment. It requires no stretch of the imagination to appreciate these visible handicaps of children just entering

school and faced with the problems of school life. It seems self-evident that a program for the periodic physical examination of preschool age children for the purpose of keeping well children well, as well as the ascertainment of existing physical defects and the eradication of the same, is exceedingly necessary and important before this child is sent to school.

A PRACTICAL HEALTH PROGRAM FOR THE PRESCHOOL AGE CHILD

What are the possibilities and how practically possible is a sound program for this group? It is, of course, easy theoretically to visualize a program for health conservation in any age group, of setting maximum standards and including in a scope of activities all of the public health services which appear to be important. We frequently, however, find this extreme not only impractical but more frequently impossible. It is the middle of the road which we must seek, and justify only the most important and necessary of services.

While we recognize the true value and importance of habit forming clinics and their significant value in this age group, we may, except in the rare instances of communities rich in appreciation of the significance in value of mental hygiene, be content with the type of mental hygiene which may be furnished by the intelligent nurse and the physician of vision, perhaps, wherever possible, guided by the trained mental hygienist.

While we know the importance of proper posture we may find it impractical to spend much money in some communities for posture clinics.

NECESSARY FUNCTIONS

What services would appear essential in a community program for the child of from 1 to 6? All public health workers grasp the full significance of value and importance of periodic medical supervision of the apparently well child. This examination serves both its primary purpose of keeping the well child well, and that of determining its physical defects and needs.

The organization of the well baby clinic is one with which you are all familiar. The place of the public health nurse who is the bridge between the home and the clinic is well recognized. Much of the child's health progress, both physical and mental, is dependent upon the intelligence and vigilance of the nurse, who can play so important a part as health educator of the family.

Opportunities for the development of proper nutrition and health habits among this group are enormous and exceedingly important for

future good health. Diet and health are intimately related and no age group furnishes so excellent an opportunity for the development of proper dietary habits and values. Faulty food habits furnish one of the perplexing problems in the field of habit formation.

Dr. Gesell informs us that the rate of mental growth in infants is indeed very rapid, and stresses the value and significance of bringing mental hygiene within the scope of the infant and child health conference. Dr. Adler informs us that habits and traits, and character itself, are formulated before the age of 5. It is difficult for every community to set up expensive mental hygiene and habit forming clinics. It is to the intelligent conference physician and equally intelligent public health nurse that communities must look for practical solutions in the fundamental principles of mental hygiene.

We hear much about dental health. We are quite reliably informed of the relativity of the temporary teeth as a guide to the proper development and occlusion of the permanent teeth. Certainly, dental prophylactic habits acquired during early child life will remain through adolescence and adult life. This emphasizes the significance and obligation for the development of dental clinics for the young.

Studies of body mechanics by the Children's Bureau have led to the definite conclusion that proper posture is an important factor in health and that the early training of body mechanics is of significant value. I am mindful again of the difficulty many health officers will have in their endeavors to justify posture clinics for the young, and yet any attempt to outline a community program for this age group must at least allude to the relative importance of posture to health. Here again the well trained nurse may do much.

One must not lose sight of the relation of the day nursery to public health and the need for medical supervision of this group of children intrusted to the care of this type of institution. I desire only to stress at this time the importance of the adequate supervision of the physical plants themselves and the opportunity provided for medical supervision.

It is important to remember that a child has a right to play. It is a natural reaction of childhood. Nature has very satisfactorily provided that there shall be an outlet for a growing child's energy, and at the same time assists in the development of mind and muscle. Particularly today our urban life, with the hazards of the street, calls for consideration for the development of recreational facilities as a part of the community health plan. I realize that one may question the responsibility of health departments for the development of recreational facilities, but one will less seriously question the use of the influence of

the intelligent health officer in the direction of the development of this very necessary community service.

We are familiar with the possibilities for the prevention of small-pox and diphtheria. One who is familiar with the progress of medicine has a reasonable right to presume that within not too long a period science will contribute much to the knowledge of the prevention of many other diseases which now appear only in a measure conquered. As science contributes to this knowledge, so will intelligent health officers avail themselves of this and regard it as part of the justifiable programs.

THE FAMILY PHYSICIAN AND PUBLIC HEALTH

No intelligent health officer fails to exercise a true mindfulness of the very significant and important part which the private practitioner—the family doctor—can and should play in the prevention of disease and the promotion of health. While the health officer cannot logically exclude from clinics supported by taxation the child of the taxpayer, he will however morally support, and will lend his material aid to a campaign for the education of the community in regard to the ability of the family physician to participate in the promotion of the public health.

CONCLUSION

May I present briefly the summary of what I would regard as a program for community health for the child of from 1 to 6, applicable to varying communities, rural or urban, leaving to others charged with the responsibility for planning, to determine as to size of area, pooling of resources, etc.?

1. The primary requisite is well qualified medical direction, whether it be the private practitioner or the pediatrician functioning in the clinic.

2. Second only to the well qualified physician is the well trained nurse fundamentally grounded in public health and sufficiently interested to perfect herself in the fundamentals of mental hygiene, posture, and other public health activities of merit. Both the physician and the nurse must play the all important part of creating a sufficient interest in the minds of the parent as to the possibilities for child health conservation.

3. Nutrition, mental hygiene and posture shall be sufficiently considered, limited in their scope only by the amount of money available for this service.

4. The significance of dental prophylaxis should be recognized by the development of facilities for not only the school child but for the preschool age youngster.

5. Allusion has already been made to recreation, supervision of day nurseries, etc. I allude at this time to tuberculosis prevention, not because of the failure to grasp its relative significance and needs, but rather because I should prefer to re-

gard it as a condition preventable through sufficient emphasis on diet, nutrition, health education, isolation, etc., as factors playing a part in the prevention of this disease.

6. Control of communicable disease by immunization, quarantine, isolation, etc.
7. Facilities for correction of defects.

It is difficult to find the yardstick with which to measure the completeness of your program. The breadth of your vision, the resources of your community—the intelligence of the people you serve, will be, I am sure, the index of your efforts. I am mindful, indeed, of your own personal interest and willingness at all times to do everything possible for the realization of this most commendable purpose and ideal, the promotion of health and prevention of disease in children.

Aeroplane Sewage Disposal

HOWARD H. BELL, M. D.

St. Louis, Mo.

I HAVE recently undertaken an aeroplane trip of approximately 2,000 miles. A toilet was available in the planes, for the use of the passengers, which consisted of a modern and comfortable seat, over a lower opening of about 6 inches in diameter which led to the great open space between the plane and the earth below. There was also a washbowl in one corner from which a drain pipe emptied into the side of the toilet bowl.

Railroads contaminate the soil notoriously over a definite course which is taken into consideration when planning the water supplies for villages and cities. Aeroplane traffic may contaminate any region, any water supply, and indeed any reservoir, in view of this promiscuous distribution of human excreta.

It seems urgent that public health authorities take immediate action to eradicate this menace to pure water supplies over our entire country. I have observed a detachable vessel to receive human excreta in British passenger planes, and corresponding or equivalent precaution should be practised by American aeroplane companies.

The Community Health Program as It Applies to the Child from Six Years to Adolescence*

WALTER H. BROWN, M. D., F. A. P. H. A.

*Professor of Hygiene and Physical Education, Leland Stanford University,
Palo Alto, Calif.*

WE are discussing the child as a whole in relation to the social group and not merely as a little organism with enlarged tonsils, carious teeth, faulty health habits, or unfortunate health attitudes. I hope we can add to this wholesome recognition of the individual a more vivid realization of the fact that our health programs must fit the child's needs and capabilities rather than have the child fit our programs.

I should like to direct attention to the present conception of a community health program, but particularly to a consideration of how a child from 6 years of age to adolescence can secure the essential health services that will enable him to develop to his highest potentiality both mentally and physically.

It may clarify our discussion if we review very briefly the evolution of what we are pleased to call a community health program. At present this term has a varied interpretation. The services it includes have been developed from differing points of view and by numerous specialized groups. This method of development of our social service institutions is inherent in the American scheme of things. It has both advantages and disadvantages. Notwithstanding the complexity of the development of the parts of the health program there is beginning to emerge a unified conception of what is essential to a well rounded community health program. A large share of the credit for the hastening of this has been due to the work of the Committee on Administrative Practice through the development and use of the *Appraisal Forms*.

A bird's eye view of the present status of our community health program can be secured through a brief discussion of 3 important

* Read before the Child Hygiene Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

phases of the American public health movement—these have been described as the sanitary, bacteriological, and personal hygiene phases.

The early stages of the sanitary phase^{*} was marked by a reign of terror caused by various epidemic diseases. With these epidemics attributed to all sorts of strange influences the methods of control were necessarily weird and ineffective. As our knowledge of the true causes of disease increased, the control of the environment scientifically yielded some of our most dramatic and effective solutions of public health problems, until today it is taken for granted that every community will see to it that all its members can be assured of pure water, safe milk, wholesome food supply and a freedom from nuisances detrimental to the public health. The danger in the taken-for-granted attitude is that some of these essential services may be neglected for some of our newer and more interesting procedures.

The growth of the science of bacteriology and its application to the control of disease marked another important phase of the health program. The discovery of the exact causes of some of our fatal maladies among living organisms opened up new possibilities of disease prevention. A gradually lengthening list of diseases has been placed in the communicable column. The laboratory has devised for us an increasing number of vaccines and serums—effective for the prevention and cure of specific sicknesses. Out of these researches have grown some of our most effective specialized campaigns against particular maladies, such as tuberculosis and venereal diseases. We have gradually developed an effective set of procedures for the control of communicable diseases; so our mythical 6 year old has a right to expect adequate protection both in the school and in the community.

Brilliant as have been the triumphs of the microbe hunters, their work has led inevitably to the last, the personal hygiene phase of the health program. This has been characterized by the turning of our attention more and more toward the individual. This change of emphasis has been brought about by the realization that further progress in disease control was dependent upon the education and the co-operation of the individual. More important still has been the increasing interest in health promotion as a part of the health program.

This period of our development has witnessed a broadening of the scope of the health program. Instead of depending entirely on the health official, we have had the extension of health work into the schools, the organization of numerous voluntary associations, and the establishment of foundations. Official and voluntary agencies have promoted maternal and infant welfare work, medical supervision of school children, public health nursing, mental hygiene and social hy-

giene. Most of these services have grown out of the special interests of small groups of people in a particular health problem.

The method of their development has frequently resulted in misunderstanding, and at times in conflict. Nevertheless we have now arrived at a period where we have available a well organized body of knowledge in each of these specialized fields, and of equal importance. We have well tested technics for the application of this knowledge. The major problem which remains is the integration of these specialized services into a well unified whole—a real community health program. It is the particular part of such a program as it applies to the child from 6 years until adolescence that we wish to discuss.

Fortunately for the child of school age, an adequate school health program is coming to be considered an essential part of a modern educational system. This is only just, when we consider that approximately one-seventh of our population is in this age group. Neither the child nor his parents have any choice as to where he shall spend this very sensitive and plastic period of his life. It is gratifying that such a large number of educators are translating the announced health as an objective of education into a functioning health program in the schools.

Our present health program in the schools has come down through a number of stages and from a variety of sources. A brief mention of some of the more important of these will serve to recall the explanation of the rather diverse and sometimes discrete health activities in the schools. The story of the evolution of these is interesting. One might begin a description at any one of a number of points. We will select the entrance of the physician into the schoolroom. He was called in as an emergency measure to try to stop an epidemic disease. Once inside the schools, he remained to discover that large numbers of the supposedly normal children had physical defects which were handicapping them both mentally and physically. While seeking to assist in solving these problems, the trained school physician has moved toward the still more important field of health promotion. Important as the work of the physician is in the schools, medical inspection alone does not constitute a health program, for you cannot inspect children into health.

Health instruction in the schools has had an interesting history. It originated as part of the effort of an interested group in fighting the use of alcohol and tobacco. In many states physiology and hygiene became required subjects. This led to a form of mechanized teaching that has been aptly called "blood and bone physiology," but with the birth of the modern health education movement, health instruction has

taken its place as one of the fundamentals of any well rounded health program, though all of us are convinced that you cannot instruct the child into health.

Our picture would be incomplete without a mention of the growth and development of physical education in its health aspects. We are all familiar with the early efforts to improve health by means of formal exercises. Then came the gradual development of a more modern plan with all of its important contributions to the improving of the functioning of both body and mind. No school could be considered as having a well rounded health program without physical education. We are sure, however, that it is not impossible to exercise children into health.

From these three main sources have arisen the widely diversified and frequently unrelated health activities in our school systems. A recent study of the character, scope and results of the school health program in representative cities in various parts of the United States has shown that there is neither uniformity nor unity in methods or administration.

Notwithstanding the wide diversity both of origin and method of health activities there has come to be a well defined opinion as to the minimum essentials we have a right to expect to be made available in every community for the child of school age. These essentials may be classified as: health instruction and training; medical supervision; hygiene of the school program; and hygiene of the school plant.

Health instruction and training are now taking their proper place in the regular curriculum of the school. We no longer expect the classroom teacher to be able to teach hygiene without special preparation. If the school health program is a good one, we will find a well planned program of training in health habits in the lower grades. As the child advances, health knowledge will be added. All of this, under skilled teaching methods, tends to the formation of ideals and attitudes that will tend to promote health.

Medical supervision of children and teachers is now recognized as an essential of every health program. If the obligation to safeguard the health of the child is to be met, it is no longer sufficient to call in the neighborhood physician on part time or in emergencies. The job of medical inspector requires special training and experience. Further, the work of the physician must be supplemented by sufficient trained and experienced public health nurses. This group of trained people will make available a system of health inspections for the control of communicable diseases. In addition, periodic health examinations of proper thoroughness will furnish a basis for the correction of

defects and an individual hygiene program adapted to the needs of the child.

The hygiene of the school program has an important bearing upon the levels of health attained by the child. Wise school administrators give careful thought to the length and arrangement of the program. The skillful use of rest periods and recesses goes toward permitting the child to make a successful hygienic adjustment to the school environment. It is fair for us to expect the health of the child to be improved rather than injured during his elementary school experience.

Finally, the hygiene of the school plant is one of the fundamentals of the health maintenance of the child. We have a responsibility to challenge the right of the state to compel the child to attend school in an improperly constructed, poorly lighted or inadequately ventilated building. Further, there is no possible excuse for the absence of proper sanitary equipment, including ample facilities for handwashing. All too frequently an excellent school plant is placed in charge of an unskilled, politically appointed, underpaid janitor. We should have janitors whose training and experience include the fundamentals of sanitary engineering.

These, in briefest outline, are the essentials of a health program in the schools for the child from 6 years to adolescence. We are all aware that some schools have parts of this program highly developed. Few have all of them functioning as a whole. This is a problem of administration. It means the placing of the health program in charge of a properly qualified person who has both the authority and the skill to weld the diverse interests and activities into a unit for the service of the child.

In conclusion, we seem justified in saying that the community health leaders should recognize the important claims of the child of school age for a high quality of health protection from the hazards of communicable diseases, impure water, contaminated milk, or unwholesome foods.

To the educators we can state that they have both a privilege and responsibility to assure this child a well rounded health program including all of the essentials which have now proved their value by the test of use.

To all of the health workers concerned with children we can appeal to participate heartily and unselfishly in the effort to integrate the diversified health activities into a unified program the sole purpose of which will be the service of the child in the effective way.

Present Status of *Acidophilus* Milk*

WILLIAM D. FROST, DR. P. H., AND T. H. BUTTERWORTH

University of Wisconsin, Madison, Wis.,

AND

STEWART M. FARR

Laboratories of Brook Hill Farm, Genesee, Wis.

ACIDOPHILUS milk continues to attract wide attention. Physicians are increasingly interested. Patients, suffering from widely differing complaints and in various stages of ill health, seek its aid.

On the other hand, the process of manufacturing acidophilus products is a difficult matter. A satisfactory product must contain an enormous number of living lactobacilli in such a vital condition that they will maintain their viability in sufficient numbers until the product is used. This apparently means that fresh strains must be isolated frequently, or at least they must be tested for their ability to implant themselves in the human intestine; and only effective strains must be put upon the market.

The possible value of sour milk as an article of diet was suggested and rationalized by Elie Metchnikoff. He studied and recommended for use a milk fermented by *B. bulgaricus*, which is still widely used in European and Asiatic countries. In America, a closely related organism has been generally recognized as possessing superior merits, and this has almost entirely taken the place of the Bulgarian bacillus.

In 1900, Ernst Moro,¹ a German investigator, found a distinctive, Gram-positive bacillus to be the predominant organism in the intestinal tract of milk-fed babies. Within the next few years his work was confirmed, the bacillus accurately described and named *B. acidophilus*. Quite recently, this germ, with its near relatives, has been transferred to a new genus by Miss Holland, and it is now known as *Lactobacillus acidophilus* (Moro) Holland.

In 1911, Rotch and Kendall² and in 1915, Rettger and his associates suggested the idea and presented evidence³ that this organism might be advantageously used instead of *B. bulgaricus*.

Since 1914, about 10 articles have appeared each year, and, in ad-

* Read before the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

dition, two books dealing exclusively with *L. acidophilus* and its applications have been published.

The authors, in view of a somewhat extended research project, have attempted to acquaint themselves at first hand with the literature on this subject. In doing this, they have consulted 182 communications which deal either with *L. acidophilus* directly, or with the intestinal flora of man and experimental animals.

One of the problems which has interested investigators since the earliest days of bacteriology has been the germ content of the intestinal tract and, especially more recently, the possibility of modifying it by change of diet. We have found 66 papers dealing with this phase of the subject. It seems fair to summarize them by saying that when an infant is born its intestinal tract is sterile, but almost immediately bacteria enter, not only through food and other contacts of the mouth, but through the anus.

If the child is breast-fed, its early heterogeneous flora soon settles down to one that is predominated by an anaerobic relative of *L. acidophilus*, now called *Bacteroides bifidus*. In bottle-fed infants, the characteristic organism is *L. acidophilus*. As soon as children become accustomed to a mixed diet, their intestinal flora comes to resemble more and more that of adults. This adult flora, most authors agree, is made up of very few Gram-positive rods, and is rather of the enterococcus and colon bacillus type. This is regarded as normal. The intestinal flora of certain individuals, especially meat eaters, is of the putrefactive type and is regarded as abnormal and very undesirable.

A few adults have what is regarded as the most desirable type, the *L. acidophilus* flora of children, or the fermentative type. The common opinion of those who have investigated the matter is that the type of intestinal flora may be modified by changes in diet, and that the fermentative type may be stimulated by consuming liberal quantities of milk and certain supplemental carbohydrates, such as lactose and dextrin. These, in part at least, pass through the small intestine unabsorbed, ready to stimulate the growth of *L. acidophilus* in the colon if this organism should be present. However, it seems clear that diet alone cannot be depended upon to establish a fermentative type of flora except in rare cases.

Another problem has attracted attention: the possibility of implanting *L. acidophilus* in the intestinal tract by the use of massive doses of this organism with an ordinary diet or in connection with certain supplemental foods. We have found 18 articles on this subject, including one book,⁴ which not only presents a great array of facts; but also carefully reviews the previous literature.

In 1926, Kopeloff's⁵ excellent book on *L. acidophilus* appeared. In this the later contributions are discussed, and new material is presented. Since then, other articles have appeared. All of this literature is quite unanimous in maintaining the thesis that massive doses of the organism taken regularly over a period of days or weeks, especially with milk or certain carbohydrates, almost invariably establish *L. acidophilus* as a predominant intestinal organism, frequently to the practical exclusion of other forms.

Milk cultures probably offer the best means of supplying effective doses, but for various reasons milk concentrates, or *L. acidophilus* in mediums other than milk, are desiderata. Several have been proposed, and some at least are promising, but up to the present time scientific literature discussing their value is lacking.

The most essential question is: When implantation has been accomplished, will beneficial clinical results follow? We find that there are about 40 articles dealing specifically with this subhead, and a number of others indirectly.

Most of these deal with the treatment of chronic constipation. The results reported, with perhaps a single exception, have been highly satisfactory. Bassler and Lutz (1922)⁶ maintain that the therapeutic value of *L. acidophilus* has been over-rated, and that benefits claimed are derived from a change in the reaction of the intestinal contents, due to the diet rather than to the presence of any organism. Their data are hardly detailed enough to be convincing. It is contrary to that of all other workers and should not be taken too seriously, since Kopeloff (1923)⁷ and Kopeloff and Beerman (1923)⁸ have quite clearly demonstrated that favorable clinical results are obtained only when fermented milk contains living organisms. The small proportion of unsatisfactory results reported may have been due to failure to secure implantation through lack of sufficient doses, or some other undetermined cause such as lack of supplemental carbohydrates. A 60 to 70 per cent change to the *L. acidophilus* type in the intestinal tract relieves constipation, and in many cases the benefits persist beyond the continuation of the culture or the carbohydrates. However, there seems to be some correlation between the permanence of the benefits and the length of time that *L. acidophilus* is recoverable from the stools. Some encouraging results have been obtained in the treatment of diarrhea and other intestinal infections.

There is still some confusion about the relation between *L. acidophilus* and its close relatives. The first American paper on this group was that of Kendall (1910).⁹ He suggested the term aciduric as better than acidophilic, claiming that the organisms "endure" rather

than "love" acid. The generic name of *Lactobacillus*, proposed by Beijerinck (1901), has recently been officially adopted. Under this genus, Bergey¹⁰ lists 35 species. There are two different types that need special mention in this connection: *L. bulgaricus* and *L. odontolyticus*.

L. bulgaricus is closely related to *L. acidophilus*, but gradually certain differences are being generally recognized. One is the action on maltose. Another was suggested by Albus and Holm (1925 and 1926).¹¹ They claim that the growth of *L. bulgaricus* is inhibited by a surface tension below 40 dynes, while *L. acidophilus* grows well in the same medium depressed as far as 36 dynes. These findings have been corroborated by Kopeloff and Beerman¹² in three papers (1926 and 1927). However, Day and Gibbs (1928)¹³ arrived at quite different conclusions. They found that any differences in the growth of the two organisms are not due directly to surface tension, but rather to the toxic action of the depressants, and are not sufficiently marked to be of service in differentiating the organisms.

On the other hand, attempts to implant *L. bulgaricus* in the human intestine have almost always failed, while *L. acidophilus* is almost always reported as readily implantable. This should be expected, since it is quite generally recognized that the natural habitat of *L. acidophilus* is in the intestinal tract, while that of *L. bulgaricus* is in some outside environment, such as milk.

L. acidophilus is regarded by some authors as the cause of dental caries. This is not only because this organism is frequently found in the presence of decaying teeth, but also because experiments have indicated that dental caries may be produced *in vitro* by *L. acidophilus*; yet, careful studies by those well acquainted with *L. acidophilus* seem to show that the organism associated with dental caries may be quite definitely differentiated from *L. acidophilus*. Considerable evidence by competent investigators indicates that this should be regarded as a distinct species, for which the name of *L. odontolyticus* has been used.

The success and popularity of *L. acidophilus* therapy have led to the manufacture of a great many products containing the organism. The most universally accepted product, of course, is milk. Whey and fruit juice, carriers of the organism, undoubtedly are of value, but as yet are not widely used.

A number of attempts have been made to concentrate the bacillus into a product of dry or semidry nature. On the whole, these have not been successful. Rettger has stated that an acidophilus concentrate that combines the salient features of acidophilus milk would be a welcome substitute.

Finally, it is quite apparent that an acidophilus product of the highest quality is one in which an enormous number of *L. acidophilus* are present; these organisms must be viable at the time of consumption; and the strain must be one that is known to be readily implantable.

Sunshine in the Laundry Bundle

PUBLIC health is being more and more prostituted by the advertisers who reach absurdities which scientific men would never suspect.

"... Now comes a laundry in the city of Chicago which promises healthful cleanliness to every home through the application of ultra-violet and ozone to linens, towels, sheets and pillow cases. The slogan is 'Year 'Round Sunshine with Fresh Mountain Air.' Apparently the application of ultra-violet rays and ozone confers longer wear on the sheets and pillow cases which are 'sun-drenched with such healthful cleanliness.' Moreover, the advertiser asserts, 'You'll like the friendly feel you'll get between fresh, crisply clean, sunsweet sheets at bedtime.' One is tempted to cogitate as to whether or not such nocturnal enjoyment might not lead to insomnia. Perhaps the Ideal Wet Wash Laundry which 'puts sunshine in the laundry bundle when it rains' will make scientific studies necessary to establish the truth or falsity of this theory."—*J. A. M. A.*, May 2, 1931, p. 1508.

Transformation of the Intestinal Flora through the Feeding of Unfermented *Acidophilus* Milk*

R. P. MYERS, PH. D.†

Research Laboratories, National Dairy Products Corporation, Inc., Baltimore, Md.

TO some who would like to take advantage of acidophilus therapy, the ordinary cultured acidophilus milk is distasteful. In view of this and also because the lactic acid in a fermented milk has been shown to have little or no value in bringing about a transformation of the intestinal flora (Kopeloff¹), it was thought that a milk product which has the taste of ordinary sweet milk and yet is a means for carrying large numbers of *L. acidophilus* into the intestinal tract would meet a real need. Such a product has been developed and for lack of a better name has been termed unfermented acidophilus milk. This product has suspended in it a high concentration of viable *L. acidophilus*; yet has the taste and physical properties of a rich whole milk. The concentration of viable *L. acidophilus* is similar to that obtained in a good cultured acidophilus milk which usually has from 100 to 600 million *L. acidophilus* per c.c. as determined by the plate method.

Unfermented acidophilus milk is handled in the same manner as market milk and is manufactured for immediate consumption, although it is stable enough to be kept in good condition for several days. Since growth of *L. acidophilus* is inhibited by a temperature of 18°–20° C., the development of acid is almost entirely prevented by keeping the milk at a temperature below 10° C. Storing the milk at 2°–5° C. makes it possible to keep it sweet for as long as 7 days.

Because sweet milk is a more favorable medium for maintaining the viability of *L. acidophilus*, unfermented acidophilus milk does not decrease in count so rapidly as the sour acidophilus milk. Counts made after 4 or 5 days' storage in a refrigerator at about 2°–5° C. show that the death rate of *L. acidophilus* under these conditions is very low. As long as the temperature is kept sufficiently low this product is stable enough to be shipped considerable distances and kept

in storage for a few days without injuring the product or destroying the viability of the acidophilus organisms. As a check on this point the unfermented acidophilus milk used in Group II of the feeding experiments was consumed when it was between 2 and 6 days old; and was capable of bringing about implantation of *L. acidophilus* in the intestinal tract.

This product is not stable unless it is kept cold, and souring is rapid at room temperature, 10° C. (or 50° F.) being about the maximum at which the milk can be stored satisfactorily. The whole milk in which the *L. acidophilus* organisms are suspended is given a higher heat treatment than is ordinarily given pasteurized milk. This reduces the con-

* Subjects in Group I.

taminating organisms to a very low count. The *L. acidophilus* organisms are grown in a sterilized medium and freed from it in such a way as to avoid contamination. They are then suspended in the pasteurized milk by procedures which reduce the chances of contamination to a minimum.

After the development of the technical side of the manufacturing process, feeding experiments were conducted with white rats. The object of these was to determine if the cells of *L. acidophilus* suspended in unfermented milk are still capable of being implanted in the intestinal tract. In general, the procedures were the same as those described by Rettger and Cheplin.² Fecal samples were examined before the feeding period by plating on tomato juice peptone agar, the plates being incubated under a partial carbon dioxide atmosphere. Whey agar shake cultures were made of various dilutions of the fecal specimens instead of Veillon tubes.

In these as well as in the experiments with human subjects our chief criterion for judging whether satisfactory implantation had been obtained was the isolation from fecal plates of high dilutions of the type of *L. acidophilus* which was being fed. We consider this method the most dependable way of determining whether implantation has been accomplished. Though we tried some of the other methods—Gram stained microscopic smears and whey agar tubes—we were inclined to put much more weight on the plate method than on the others. The

results were as follows: Successful implantation was obtained in 4 white rats fed, in addition to the bread and meat diet, 5 c.c. of unfermented acidophilus milk daily. Two of these were put on a bread and meat diet at the end of the 2 weeks' feeding period. After they had been on this diet for a month, and were found to have no *L. acidophilus* in their feces, they were again fed unfermented acidophilus milk and successful implantation was obtained within a week. Two rats were fed 5 c.c. of a cultured acidophilus milk for comparison, and successful implantation was obtained also in these. These preliminary results indicated that the organisms suspended in unfermented milk were not injured in the manufacturing process and were capable of being implanted in the intestinal tract.

The next step was to determine: (1) whether the lactobacilli which were suspended in unfermented acidophilus milk can be implanted in the human intestinal tract, and (2) to what extent the human intestinal flora can be transformed to a simplified Gram positive type by the regular feeding of unfermented acidophilus milk. Two groups of experiments in which 11 individuals drank unfermented acidophilus milk for periods of 3 weeks were conducted. The first group lasted from May 6 to May 24; the second from September 4 to September 23. In the second group were included 5 individuals who were also in the first. Most drank a quart of unfermented acidophilus milk daily, though some varied from this amount and occasionally went for 2 or 3 days without. However, on the whole, the consumption of milk was regular. Each person continued on his regular diet, though some remarked that the amount of their regular diet was decreased.

With the exception of No. 11, a woman, all were men. Nos. 7 and 10 were slightly under 20 years of age, No. 5 was elderly, the others were in their third decade. The subjects were healthy and normal except that a few were subject to slight constipation.

Examinations were made of fecal specimens before the subjects began drinking the unfermented milk, and thereafter every 4 or 5 days. Tomato juice peptone agar or digested milk agar plates were used in determining the number of viable cells of *L. acidophilus* per gm. of fecal material. Smears stained by Gram's method were prepared and observed but no counts were made.

Tables I and II show the percentages of acidophilus present in the feces, and in Tables Ia and IIa are recorded the *L. acidophilus* counts per gm. of fecal material. Tables III and IV give information on the unfermented acidophilus milk used.

TABLE III

UNFERMENTED ACIDOPHILUS MILK USED IN FEEDING EXPERIMENTS

" 17	6.35	800,000,000
" 20	—	156,000,000
" 22	6.15	265,000,000
		Average 340,000,000

In all the experiments *L. acidophilus* of the X-type was used, though different strains were employed. These grow readily in milk, and a 2 per cent inoculation brings about curdling in from 16 to 18 hours' incubation at 37° C. They grow in digested milk at pH 8.0, and tolerate a concentration on phenol of 1:400 and a concentration of indol of 1:1,420. The colonies on tomato juice peptone agar are extremely filamentous. Culture RL8A (used in Group II of the human experiments) tends to grow slightly more compactly than the others. These cultures are Gram-positive slender rods occurring singly, in pairs and occasionally in chains of 3-4.

SUMMARY AND CONCLUSIONS

1. It has been shown that the cells of *L. acidophilus* which are suspended in unfermented acidophilus milk are capable of being implanted in the human intestinal tract. It appears, then, that the process of manufacture does not injure the viability of the organisms and that the most important consideration is the use of a strain of *L. acidophilus* which is adapted for growth in the intestine.

2. In the 16 experiments on human subjects, successful implantation of *L. acidophilus*, as determined by the plate method, was obtained in each case. In 12 of the 16 experiments a predominant *L. acidophilus* flora was obtained by the regular consumption of approximately 1 quart of unfermented acidophilus milk per day, no other modification of the ordinary diets of the subjects having been made.

Studies on the Viability of *L. acidophilus* in "Acidophilus Milk"

WALTER L. KULP, PH. D.

Department of Bacteriology, Connecticut Agricultural College, Storrs, Conn.*

EXPONENTS of acidophilus therapy agree that, regardless of the method of administration, satisfactory therapeutic effects are dependent upon the use of cultures which contain large numbers of viable organisms. Those who have opposed the employment of broth cultures and various so-called concentrates have maintained that these preparations may fail in part because they do not preserve the viability of *L. acidophilus* for any appreciable length of time. Long experience with acidophilus milk has shown that milk constitutes a particularly favorable medium for the growth and continued viability of this organism.

It seems to be the consensus of opinion that acidophilus milk should contain at least 100 million viable organisms per c.c. when it reaches the consumer. When authentic and vigorous strains of *L. acidophilus* are employed, properly prepared acidophilus milk should contain from 500 million to 1 billion viable bacilli per c.c. at the time the product is bottled. It is essential that the producer maintain a high viability in his product in order that the consumer may secure the full therapeutic effect. When the manufacturing plant is so located that the milk can be used within 48 to 72 hours after preparation, this is relatively simple. However, under present methods of distribution a considerable quantity is from 3 days to 2 weeks old before it is used. It is imperative, therefore, that the product be of the highest purity and viability in order to meet the most rigid requirements during storage.

Commercial acidophilus products are being examined by state and federal laboratories, and it is quite possible that in the near future legislation will be enacted which will require them to meet certain standards, particularly as regards viability.

Kopeloff and Berman¹ studied the effect of storage temperature on *L. acidophilus* in milk, and claimed that there is an enormous decrease in the number of viable bacilli when acidophilus milk is stored in the refrigerator, and that this does not take place when stored at ordinary

* The greater part of the work reported in this paper was completed in the laboratories of the Yale University School of Medicine where the author was Assistant Professor of Bacteriology until July 1, 1930.

room temperature. Hence, they recommend storage at room (20–30° C.), instead of icebox, temperature. Since the commercial distribution of acidophilus milk has attained considerable proportions, it appeared advisable to make further inquiry into the question of viability of *L. acidophilus* during prolonged storage.

It is impracticable for the producer of commercial acidophilus milk to store this commodity at room temperature because (1) The commercial product is rarely pure culture. Given a small initial contamination, and high *L. acidophilus* count, storage at room temperature (above 20° C.) may cause a decided increase in the numbers of contaminating forms, with resultant damage to the milk on account of the corresponding decrease in number of viable *L. acidophilus* cells which naturally takes place, and as a rule the production of "off" flavors and odors. (2) Storage at room temperature promotes the continued action of saccharolytic enzymes, with resultant increase in acidity. Within a few days the milk may become so sour as to be unpalatable.

Since acidophilus milk does not appreciably change in acidity at temperatures below 20° C., and since lower temperatures will inhibit or at least greatly retard the growth of most contaminating forms, particularly in a medium as acid as this normally is, the writer has sought storage conditions which will conserve the maximum viability of the organism without changing to any great extent the specific characteristics of the product.

An authentic human strain of *L. acidophilus*, typical in all respects, was employed in the majority of the experiments reported, though several other strains of either human or rat origin were used in some of the comparative tests. All strains gave essentially the same general results. Typical *L. acidophilus* organisms have the following characteristics:

They are non-motile and non-sporing, Gram-positive rods which produce chiefly lactic acid in milk with traces of acetic acid, forming acid without gas in lactose, galactose, sucrose, maltose and levulose broths. The optimum temperature is 37.5° C., the minimum close to 20° C. Colony formation in special agar medium³ is commonly of the rough or X-type, as described by Rettger and Horton.⁴ Incubation in an atmosphere containing approximately 10 per cent carbon dioxide⁵ enhances the growth of most strains; CO₂ is detrimental to none, and is necessary for some. When ingested along with lactose or dextrin, they will grow in the digestive tract of man, and may be recovered from the feces.

In the present investigation the main emphasis was placed on via-

bility as affected by: (1) initial and final reaction of the product, (2) storage temperature, (3) incubation temperature, and (4) butter fat.

The quantitative determination of living *L. acidophilus* was made according to the method of the author.² Tomato agar³ was employed as the plating medium. Since the counts are very high, the error is obviously considerable and numbers are at best only relative. Accurate counts of *L. acidophilus* in milk cultures are out of the question, and differences of 10 or 15 per cent in duplicate platings are the rule rather than the exception. The acidity of the milk is expressed in percentage lactic acid as determined by titration with $n/20$ NaOH, phenolphthalein being the indicator. The number of viable *L. acidophilus* is recorded in all tables as millions.

Certain variation in counts should be discussed. In the course of many experiments the viable count determined after 1, 2, or 3 days' holding was greater than at the initiation of storage. This variation may be due to the acknowledged inaccuracy of the plating method. There also may be some multiplication during the first few hours of storage before the milk has reached the temperature of the chamber.

EXPERIMENT I

The influence of varying initial reactions upon the viability of L. acidophilus in milk culture stored at 12° C. and at room temperature, 23° C.

Eight flasks of sterilized skimmed milk were inoculated with *L. acidophilus* as follows: 2 at 8:10 A.M., 2 at 10:10 A.M., 2 at 12:10 P.M., and 2 at 2:10 P.M.; and after shaking were at once placed in a 35° C. incubator. Quantitative platings and titratable acidity determinations were made from one flask of each pair at 8:10 A.M. on the following day, after this one was stored at 12° C. and the other at 23° C. Viability and acidity were determined at stated intervals.

In this experiment (Table I) Kopeloff's claims regarding viability are supported to a certain extent. Viability of *L. acidophilus* continued higher at room temperature than at 10–12° C. during the earlier period of storage. After prolonged holding the results are reversed. However, after continued storage the acidity of the milk kept at room temperature had increased from 2 to 3 times as much as that held at 10–12° C. The initial acidity, or some metabolic product associated with the development of high acidity, plays a considerable part in determining the sustained viability during storage, which decreases at a rate somewhat proportional to the initial acidity. Rogers⁴ reported that *S. lacticus* elaborates a chemical substance which is inhibitive to itself and to *L. bulgaricus* as well. The same sort of factor may operate in the case of *L. acidophilus*.

EXPERIMENT II

The viability of L. acidophilus in milk cultures of varying initial acidity when stored at 5° C.

Three flasks of sterilized skimmed milk were inoculated with like amounts of *L. acidophilus* milk cultures at different hours during the

TABLE II

SHOWING THE EFFECT OF VARIED INITIAL ACIDITY UPON THE VIABILITY OF *L. ACIDOPHILUS* AT 50° C.

Time Inoculated.....	8 A.M.			2:30 P.M.			5:30 P.M.		
Length of Storage at 5° C.	Count per c.c.	Per Cent Decrease	Acidity in Per Cent	Count per c.c.	Per Cent Decrease	Acidity in Per Cent	Count per c.c.	Per Cent Decrease	Acidity in Per Cent
At beginning	700	—	0.9	285	—	0.5	135	—	0.37
2 days	435	40.0	0.9	285	none	0.5	125	7	0.37
8 days	35	95.0	0.9	250	12	0.5	100	26	0.37
13 days	0	99.0	0.9	130	54	0.5	115	15	0.37
17 days	0	99.5	0.9	90	70	0.5	80	40	0.37
30 days	0	99.9	0.9	50	82	0.5	45	65	0.37

day. After incubation at 35° C. until 9:00 A.M. of the following day, the count and the titratable acidity of the milk in each flask were determined. These flasks were then stored at 5° C. Platings and acidity determinations were made at definite intervals during a storage period of 1 month.

It may be concluded from a study of Table II that high acidity or related factors present at the initiation of storage cause a rapid decrease in the number of *L. acidophilus* at 5° C. Conversely, a low acidity enhances the viability of this organism when stored at the same temperature.

EXPERIMENT III

Influence of different storage temperatures upon the viability of L. acidophilus in milk cultures of the same initial acidity.

Separate portions of a batch of acidophilus milk were stored at

different temperatures for a period of 3 weeks, during which viability and titratable acidity were determined at stated intervals.

The results of Experiment III are not exactly consistent with those of Experiment I, since they show to a slight extent a reverse relationship between storage at 23° C. and at 10–12° C. during the shorter periods of holding. These slight discrepancies can probably be attributed to the considerable inaccuracy in any quantitative method employed for determining living *L. acidophilus*. This experiment again indicates the considerable increase of acidity at 23° C., and shows that storage at 18° C. preserves a high viability of *L. acidophilus*, with no increase in acidity.

EXPERIMENT IV A

The influence of ripening temperatures upon the viability of L. acidophilus in milk cultures during storage.

Six flasks of sterilized milk were warmed to 38° C. Then each received an equal amount of *L. acidophilus* inoculum. Two were incubated at 35° C., 2 at 37° C., and 2 at 40° C. After 20 hours all were removed from the incubator. Viability counts and acidity determinations were made on 1 in each pair; 1 was stored at 5° C. and the other at 20° C. Viability counts and acidity determinations were made at stated intervals during 7 days.

TABLE IV A

SHOWING INFLUENCE OF DIFFERENT RIPENING TEMPERATURES UPON THE VIABILITY OF *L. ACIDOPHILUS* IN MILK CULTURES DURING STORAGE

EXPERIMENT IV B

This differed from IVA in that each pair of flasks containing sterilized milk was inoculated at a different hour during the day in order .

that the acidity of all the milk after ripening would be practically identical.

The results of Experiment IV indicate that the ripening temperature influences viability of *L. acidophilus* only in so far as increased acidity is concerned, and again demonstrates the weakening effect of high initial acidity or closely related factors upon *L. acidophilus* in storage. The organisms in the high acid milk died off more rapidly at 5° C. than at 20° C. However, the decided increase in acidity in 20° storage is highly undesirable.

TABLE IV B

EXPERIMENT V

The influence of butter fat upon viability of L. acidophilus in milk cultures during storage.

Two flasks of skimmed milk, 2 of milk containing 1 per cent butter fat and 2 of milk containing 4 per cent butter fat were inoculated with *L. acidophilus*. After 20 hours' incubation at 35° C., 1 of each pair was stored at 11° C. and the other at 20° C. Viability counts and reactions were determined for each flask at intervals during a storage of 3 weeks.

The results apparently demonstrate that the amount of butter fat has no appreciable effect on the viability of *L. acidophilus*.

EXPERIMENT VI

The acidophilus milk employed in all experiments reported thus far was prepared in the laboratory from a pure culture.

It appeared desirable to determine the viability of *L. acidophilus* in the commercial product under different storage conditions. Two shipments of acidophilus milk were secured from two producing concerns. These lots were chosen at random at the distributing points and sent to our laboratory. Shipment A was sent by parcel post. It was bottled January 24 and received at our laboratory January 26. The initial count per c.c. was determined January 27, when the con-

NOTE: In this table the *L. acidophilus* count is given in millions as in all other tables. The count of contaminants is the actual numbers per c.c.

trolled storage was begun. It was, therefore, 3 days old at this time.

Shipment B was delivered to us by express and was well iced during transit. This was 2 days old when the controlled storage experi-

ment began. The effect of storage temperatures on contaminating forms in B was determined.

Experiment VI is a practical demonstration of the effect of different storage temperatures upon the viability of *L. acidophilus* in commercial acidophilus milk.

At the completion of the storage period there was no apparent change in the flavor, acidity, etc., of the samples kept at 5° C. and 8° C. Samples of "A" stored at 20° C. and at 25°–27° C. did not have any "off" flavor or taste, but were too sour to be palatable. The taste of "B" kept at these same temperatures was decidedly "off" in addition to an excessive acidity. The large numbers of foreign bacteria developing at these higher temperatures were without doubt responsible for the "off" flavor.

DISCUSSION

Close inspection of the results reported in this paper should reveal several points of practical significance to those who are interested in the production and use of acidophilus milk.

The first and probably most important conclusion is that the maximum viability of *L. acidophilus* manifests itself in the freshly prepared product, with a fairly rapid decrease within any storage period. However, if we accept a required minimum of 100 or even 200 millions of viable organisms at the time of consumption, it should be stated in fairness to producers of high grade acidophilus milk, that reasonably satisfactory viability can be maintained for 2 or even 3 weeks without serious harm to the product. The maintenance of this standard for such periods requires strict adherence to certain rules governing proper preparation and storage.

From a strictly scientific standpoint, the observations of Kopeloff and Berman regarding viability of *L. acidophilus* during short storage periods are in a measure correct. However, only in rare instances during our experiments have the numbers of living *L. acidophilus* decreased after 3 days' storage to the extent reported by these investigators. From a practical viewpoint their recommendation for storage at room temperature is unwarranted and unnecessary, and if carried out would probably do the commercial product more harm than good.

The term "room temperature" is too variable in interpretation. So-called "room temperatures" range ordinarily from 18° C. to 30° C. It is quite probable that the continued high viability of *L. acidophilus* at "room temperature" is not a question of maintenance of the original organisms but is due to continued multiplication. The rate of this increase is dependent upon the temperature increment above 20° C.

The metabolism of *L. acidophilus* at temperatures above 21° C. is sufficient to cause an actual increase in numbers up to a maximum, but at the expense of the palatability due to an excessive increase in acidity. Over comparatively long storage periods at any temperature this increased acidity or the development of other metabolic products is markedly detrimental to viability. In addition, storage at room temperature may bring about the rapid development of contaminants, with resultant lowering of the efficacy and palatability of the product.

CONCLUSIONS

From the standpoint of palatability of *L. acidophilus* milk, the continued life of *L. acidophilus* in storage seemed to depend upon two factors—initial acidity or some related metabolic substance, and storage temperature, assuming that there is a minimum of contaminating growth. In order to insure satisfactory viability for 2 days to 1 week, commercial acidophilus milk of good quality may be stored at 5° C., provided the acidity at the time of bottling is not more than 0.65 per cent.

When the producer of acidophilus milk desires a satisfactory viability of *L. acidophilus* for more than 1 week, the following rules must be closely followed:

The number of foreign bacteria must always remain at a negligible figure.

Rigid precaution against excessive acidity must be observed.

The storage temperature should range between 12° C. and 16° C., the optimum viability temperature for *L. acidophilus* in milk being 16° C. when the initial acidity is 0.65 per cent.

Diphtheria Immunization by Three and Four Injections of Toxin-Antitoxin

Comparative Trend of the Immunizing Process

V. K. VOLK, M. D., D. P. H.

Deputy Commissioner, Oakland County Department of Health, Pontiac, Mich.

THE impression which has prevailed that 3 injections of diphtheria toxin-antitoxin are sufficient in a very large majority of cases to produce immunity in the course of a year or less has not been corroborated by our work in Oakland County rural schools.

The results of the immunization of over 8,000 children in the past 4 years were disappointing inasmuch as only 65 per cent of those given 3 injections became immune at the end of the first year.

Not being entirely satisfied with the results shown at the end of the first year by the use of 3 injections of toxin-antitoxin, we began the use of 4 injections in 1928 with the hope of obtaining more satisfactory results. A study was made to determine to what extent the trend of the immunizing process differs in two groups of children who received 3 and 4 injections of toxin-antitoxin: (1) at the end of the first year, and (2) at the end of the second year.

Four intramuscular injections of 1 c.c. of toxin-antitoxin were given to 946 rural children comprising a typically American group. Those children who for various reasons failed to receive the 4th injection comprised the other group of 336 children receiving 3 injections of toxin-antitoxin.

No preliminary Schick test was given because of the known high percentage of susceptibles. On other occasions when large groups of rural children were Schick tested about 94 per cent were found Schick positive. Toxin-antitoxin and diphtheria toxin for Schick test were furnished at all times by the Michigan Department of Health. The Schick test which was given 1 year following toxin-antitoxin was read by the writer throughout to insure uniformity of interpretation. The Schick test was read 1 week later than the injection to eliminate as far as possible the pseudo reactions.

Although we were aware of the fact that pseudo reactions occasionally last for more than 7 days, no controls were used. However,

the possibility of misinterpretation, though small, would exist to a similar degree in both groups and therefore would not affect the correct evaluation of the trend of the immunizing process.

The results of immunization by 4 injections of toxin-antitoxin as well as the comparison with results obtained by 3 injections are shown in detail in Figure I.

It will be noted that while 35.4 per cent of those who received 3 injections were still susceptible at the end of the year only 26 per cent of those who received 4 injections were susceptible at the end of the same period of time.

*TABULATIONS OF RESULTS OF IMMUNIZATION
BY THREE AND FOUR INJECTIONS OF TOXIN ANTITOXIN*

AGE GROUP	CHILDREN	NUMBER OF INJECTIONS			
		3		4	
		+	-	+	-

	%	35.4	64.6	26	74

FIGURE I

Careful follow-up work was done on 114 cases that received 3 injections of toxin-antitoxin in 1928 and which were found to be Schick positive 1 year after the administration of toxin-antitoxin. This group was Schicked again a year later, in 1930, and the results thus obtained reveal that 48 children, or only 42 per cent, remained positive at the end of the second year.

In the group of 946 children who received 4 injections of toxin-antitoxin in 1928, 247 were positive 1 year later; of this group 131 were carefully studied. At the end of the second year when this group of 131 was re-Schicked, 42 children, or only 32 per cent, remained positive.

Comparison of the results obtained at the end of 24 months in both groups comprising 245 Schick positive children indicates that 4 injections of toxin-antitoxin promote the development of immunity at the end of the second year to a greater degree than do 3 injections; of the Schick positive group which received 3 injections of toxin-antitoxin, 58 per cent changed to negative; while of the Schick positive children of a similar age group who received 4 injections of toxin-antitoxin 68 per cent changed to negative.

In the Schick test we have a definite means of determining susceptibility to diphtheria at the time the test is given. However, the susceptibility to diphtheria is lessened as time goes on and to a greater degree, in those who received toxin-antitoxin, with the ultimate result that immunity is built up, as shown in Figure II, from 64.6 per cent at the end of the first year to about 85 per cent at the end of the second year in those who received 3 injections of toxin-antitoxin, from 74 per

cent at the end of the first year to about 92 per cent at the end of the second year in those who received 4 injections of toxin-antitoxin.

It would appear that toxin-antitoxin is the most active factor in the progressive trend of the development of immunity since both groups could be equally affected by other contributory factors to immunity such as the natural development of immunity as age increases and the less important factor of mingling with unrecognized cases of diphtheria or diphtheria carriers.

In the practice followed by the great majority of health officers of giving the Schick test 6 months to a year after toxin-antitoxin, with the additional administration of toxin-antitoxin should the Schick test be found positive, an important factor is disregarded or at least not emphasized; the result of immunization is not final during the first 6 months or a year. Failure to consider this factor has resulted in a lowered estimate of the number of cases which ultimately become immune and has often led to the unnecessary administration of an additional series of toxin-antitoxin.

Inasmuch as it is probable that, because of the progressive trend of immunity, the Schick reaction will ultimately change to negative by the end of the second year in a large percentage of cases, it appears premature to give the Schick test at the end of the first year. On the other hand, it is obviously a difficult matter to give the Schick test 2 years after the administration of toxin-antitoxin because of the shifting school and preschool population.

What possible disadvantages may be encountered in omitting the Schick test? A survey concerning the re-Schicking practice in 104 cities made by Armstrong and Walker indicates that, even with the present routine, less than 35 per cent of children receiving toxin-antitoxin are subsequently Schick tested. Parents are advised that the child, after receiving toxin-antitoxin, will probably be protected against diphtheria, but because of the possibility that

STATUS OF IMMUNITY IN TWO GROUPS OF CHILDREN AT THE END OF 12 AND 24 MONTHS AFTER 3 AND 4 INJECTIONS OF TAT
FIGURE II

he might not be, they should consult the family physician should there be any evidence of sore throat. This point of view is in accord with

Park, who, in his book, *Public Health and Hygiene*, in discussing what should be done with a child who has received toxin-antitoxin or who has been shown to be immune by a negative Schick test, states:

If the child should develop a suspicious sore throat, it should then receive antitoxin even though the probability of the condition being diphtheria is very slight. There is no serious objection to giving the child an unnecessary dose of antitoxin, and it is known that serious harm may ensue if the child develops diphtheria and an early dose of antitoxin is not given, since we know there are slips with the Schick test.

An additional reason why this procedure should be carried out faithfully is the fact that Park, Parish, Okel and others have observed that the dictum "Once Schick negative always Schick negative" is an assertion subject to exceptions and that between 3 and 5 per cent of children previously Schick negative were found to be Schick positive upon re-testing.

Park, Scamman, Gordon, Schwalbe and others relate authentic cases of clinical diphtheria in persons previously Schick negative. This may be accounted for by the fact that the average amount of antitoxin in the system which is responsible for Schick negative reactions might have lessened since the test was done or occasionally be insufficient to withstand an unusually severe infection.

Factors such as smallpox vaccination (observation by Finkelstein) or an attack of scarlet fever (observation by Hull), are also apt, in their opinion, to change the Schick test temporarily at least from negative to positive by temporarily decreasing the diphtheria antitoxin in the body.

Kellogg's observations led him to the conclusion that the Schick test should be abandoned for routine use for a number of reasons, among them being the possibility of error in interpretation because of protein sensitization, local differences in the immunity of the tissue, etc.

The possibility of these occurrences though extremely rare should not be overlooked.

A study made by Gordon of 1,500 cases admitted to Herman Kiefer Hospital reveals that only 14.7 per cent gave history of having received toxin-antitoxin. The ratio of population of the groups receiving toxin-antitoxin and not receiving toxin-antitoxin indicates that a little over 50 per cent of school and preschool children in Detroit received toxin-antitoxin. Thus for each 6 or 7 cases of diphtheria which occurred in the unprotected group, there was but 1 case of diphtheria in the group that received toxin-antitoxin. The study is not complete, but information available as to how long toxin-antitoxin had been

given before diphtheria developed indicates that over 40 per cent of those having diphtheria received toxin-antitoxin less than 6 months previously.

A careful follow-up of the group termed "immunized" will probably reveal, according to Detroit health authorities, that many who gave a history of toxin-antitoxin had received some other injections instead; thus the presumably immunized group would be materially decreased. The reduction of diphtheria mortality in the group that previously received toxin-antitoxin is also quite impressive since it is only one-third of the prevailing mortality rate among those who did not receive toxin-antitoxin.

The study of Scamman and Pope on "Diphtheria Immunization of 15,000 Children in Providence" strikingly reveals that the incidence of diphtheria among the children who received 3 injections of toxin-antitoxin is 10 times less than that among the similar group of children that did not have toxin-antitoxin. It is reasonable to expect even better results with 4 injections of toxin-antitoxin.

The omission of the Schick test as a routine procedure is indirectly in accord with the present trend of encouraging the private practitioner to assume the responsibility of immunization. When the work of immunization is finally delegated to the family physician, to whom it rightfully belongs, he would be relieved of the necessity of making a delicate test and would be encouraged to urge toxin-antitoxin since there would be no necessity for following it up. The faith of parents in toxin-antitoxin would be enhanced since it would become common knowledge that 4 injections are all that is necessary in a large majority of cases.

The practice of omitting the Schick test altogether has been used with success in some communities. It seems justifiable under normal conditions, except perhaps among school children in large cities, to omit the Schick test because the health officer would thus be enabled to enlarge the group of protected children.

Under normal conditions the health officer is concerned with the community status of immunity and his efforts should be directed toward decreasing susceptibility to diphtheria in the community because it is well known that in spite of the most efficient epidemiological measures and practices, the majority of cases cannot be traced to a definite source of infection. This is shown by Benning in his study of 500 consecutive cases of diphtheria in Baltimore of which 77.6 per cent could not be traced to any definite source.

It should not, however, be implied that the Schick test should be omitted in times of unusual prevalence of diphtheria in a community

or institution where conditions are favorable for the spread of the disease, where it is necessary to know the exact status of immunity at all times, or for preliminary testing. It would, of course, remain an indispensable factor in research work.

SUMMARY

Studies to ascertain the development of immunity against diphtheria were carried on among 1,282 children. Group one, 336 children, received 3 injections of toxin-antitoxin and showed immunity after the first year in 64.4 per cent and after the second year in about 85 per cent. Group two, 946 children, received 4 injections of toxin-antitoxin and showed immunity after the first year in 74 per cent and after the second year in 92 per cent.

Four injections of toxin-antitoxin do not produce any more untoward reaction than 3 and are not impractical either in private practice or as a public health procedure in schools.

The use of 4 injections appears to be a preferable method of toxin-antitoxin administration until diphtheria toxoid has been sufficiently tested to justify its use in either preschool children alone or in all groups and ages.

The Schick test need not be given as a routine procedure at the end of the first year, if at all, after administration of 4 injections of toxin-antitoxin.

Simplifying the procedure by the omission of the final Schick test would encourage the private physician to undertake the work of immunization. The time saved by the omission of the final Schick test would enable the health officer to reach a larger group of unprotected children.

The Schick test would, of course, remain an indispensable test in research work, preliminary testing, in times of unusual prevalence of diphtheria in communities or institutions where conditions are favorable for the spread of the disease, or where it is necessary to know the exact status of immunity at all times.

These observations, though based on too small a group of children to justify drawing final conclusions, indicate a definite trend in the progress of the immunizing process after the first year to a much greater extent than has been commonly assumed and it is earnestly hoped that others will be stimulated to carry on similar studies.

Drought Area

DURING the fiscal year beginning July 1, 1931, we shall have available for co-operative work in the drought-stricken area approximately \$1,500,000, or such part thereof as may be necessary. For the counties not included in this area there will be available the regular rural sanitation appropriation of \$338,000. Estimates and budgets for proposed projects under each of these appropriations were requested early in May, for the coming fiscal year, and those approved will become effective July 1, 1931. The possible total, therefore, which the public health may have invested in coöperative county health work during the year July 1, 1931, to June 30, 1932, is approximately \$1,838,000.

* * * * *

As regards the consultation and advisory service there can be no doubt of the value of professional advice and assistance to communities and states by competent experts in the several phases of public health. Such service is now being organized on a modest scale in connection with the drought relief work, and its value and possibilities will be readily apparent to those of you to whom it is possible to extend it.—Assistant Surgeon General W. F. Draper, *United States Daily*, May 9, 1931.

What Social Work Is Not

ELEANOR E. KELLY

Supervisor of Social Service, State Department of Public Health, Boston, Mass.

SOCIAL work has been called many things. Here are seven things to remember that social work is not:

1. Social work does not signify social secretarial work; nor is it to be construed as in any sense related to the activities of the so-called society world. Social workers are recruited from all walks of life and their profession is not limited in scope of service to any particular class or creed.

2. There is a misconception of social work as the doling out of material relief by a "Lady Bountiful."

Of course, there always has been and always will be in the world a place for the individual who, from his plenty, is ready to give to those who are in need. Without this spirit the world would be a sorry place indeed, and professional social workers would be at a loss to find the funds for necessary relief. It is not, therefore, this spirit of giving with which we quarrel, nor do we want to belittle the value of the gifts or the sincerity of purpose. It is necessary, however, to explain that relief giving is not the sole function of the social worker. Money is, naturally, one of the tools with which she works but it is not given or withheld according to the fullness or emptiness of the exchequer—or merely on an impulse.

The professional social worker is trained in the scientific method of handling her problems. For instance, a man asks for the price of a meal for which he honestly cannot pay. The social worker immediately says to herself: "Why is this man in need? How much better off will he be if I give him money for one meal? What can I do to be of real help to him?" The man may be ill or out of work. It would be easy to give what he asks and dismiss the matter. But how much more effectively she can help if she understands his real need! If she learns that he is out of work, she endeavors to help him in his search for a job.

If he is physically unable to work, she will first arrange for him to secure medical treatment. Later she will put him in touch with employment bureaus or help him to make whatever other adjustment may be indicated in order that he can carry on for himself. This of

necessity requires time, and the man must be given aid until he is able to stand on his own feet. It is a decidedly better investment for the social worker to spend time helping him to work out his own problem than to encourage him to go from one individual to another seeking help which will suffice only for the moment.

If he is a professional tramp, he will not respond to social treatment by the scientific method. The self respecting individual, however, who is down on his luck through misfortune, weakness, or ill health, welcomes the chance to do his part and will often redouble his own efforts when he feels that some one is trying to help in an understanding way.

3. I want to stress the fact that the social worker is not a meddler, making unnecessary inquiries merely out of curiosity, or a desire to prove the individual or family unworthy of aid. She investigates in order to determine the need and formulate an intelligent plan whereby she can meet that need.

The business man satisfies himself as far as possible that a contemplated investment is a sound business proposition. The social worker invests time and energy in working out a social problem. She must have reasonable expectation of satisfactory returns in the social adjustment she seeks. Besides, she is responsible for her expenditure of time and money to the public, to whom an injustice is done if she does not use them wisely.

Frequently the social worker is called upon to help in some home adjustment. It is difficult enough to advise and assist a family when all the facts are at hand. To try to do so without a knowledge of the true family situation may lead to a wholly inadequate or unfair solution, such as the placing of too great a burden upon an individual, or an unjust shifting of responsibility to the community.

Again, in making plans for the child who has no family, it is of vital importance both to the child and to the foster parents that the personnel, the environment, and the moral and physical aspects of the home be suitable. It is unfair, for instance, to place a child in a home in which his moral or physical welfare is not assured. It is just as unfair to the parents to admit to their home a child who may be a physical or moral menace to their own children. Careful investigation is necessary for the protection of the family and the needy child.

In every form of social work, it is essential that the worker shall learn what the need is, what has caused the need, and what resources she can call upon besides her own skill and ingenuity. All her efforts are based on a desire to be of service, and to meet the need with the

most effective, constructive plan possible. There are, of course, blunders in social work as there are in all fields of endeavor, but fortunately they are not representative of the group.

4. There is a special type of social service, medical social work. This is not identical with nursing, although these fields are very closely allied. The medical social worker does not concern herself directly with the physical care of the patient. The basis of her work is the medical need of the patient, but the service she renders is social treatment.

She brings to the attention of the doctor significant data regarding the patient's environment, family and responsibilities—information which aids the doctor in making a diagnosis or recommending treatment. Then she helps the patient to carry through the plan of treatment ordered by the doctor. The social worker first ascertains whether it is possible for the patient to follow the doctor's directions, for hospitalization, treatment or rest, or hygienic living. If not, she must try to remove whatever obstacles there may be. It is futile, for example, for the doctor to advise a long rest for a man who must support his family and cannot give up his job. Unless some help can be given him, he will not have the necessary medical attention and before long will be physically unfit for work. It is the responsibility of the social worker to help him in making a temporary plan for his family so that he can have the necessary rest.

Sometimes the social worker will need to explain a patient's condition to the family and secure their help in placing him under treatment. Often she helps the patient to understand the medical plan. The problems presented to the medical social worker are many and varied, but always she must consider the individual patient with his medical problem in his relationship to his family and the community. Whether the social worker is found in the hospital, clinic, or health department, she strives to help the sick individual to make such adjustments as will speed his return to health, and the well person to live in such a way that his health will be protected.

5. The social worker has no panacea. When a problem is presented to her, she uses every known resource in her effort to solve it, but she does not always realize her hopes for the individual or group in need. She does not work alone. Health agencies, relief agencies, settlements, churches, and many other organizations rendering specialized services may be called upon to advise and assist her. Without this team play, constructive accomplishment would be difficult. Even with her best efforts, however, it is not always possible to stimulate in an individual that which will enable him to win out for himself.

6. Again, the efforts of social workers are not limited to case work. Through service to the individual and the group, they become cognizant of existing unsatisfactory social conditions and bring these before the public for remedy. Some of our soundest legislation has been the outgrowth of such service.

7. Social work is not and never can be divorced from spirituality. The very foundations of social service rest upon man's need for expressing his religion. In service to his fellowmen, he satisfies in a small measure this need. Sometimes the motive seems to be lost sight of in the necessity for practical methods but underlying there is the fundamental element of spirituality.

Social work has been described as "any form of persistent and deliberate effort to improve living or working conditions in the community, or to relieve, diminish or prevent distress, whether due to weakness of character, or to pressure of external circumstances. All such efforts may be conceived as falling under the heads of charity, education or justice, and the same action may sometimes appear as one or another according to the point of view."

Laval University (French College), Montreal

Hygienic and Sanitary Features of Milk Production by the Rotolactor Process

JOHN G. HARDENBERGH, V. M. D.

The Walker Gordon Laboratory Company, Plainsboro, N. J.

MENTION was made in the December, 1930, issue of the *Journal* (p. 1389) of a new system of producing milk by means of the "Rotolactor," developed and used by the Walker-Gordon Laboratories, Plainsboro, N. J. Since this system embodies several features which contribute unusual sanitary safeguards to the production of clean milk, the following survey of the process is of interest to health officers and other readers.

The rotolactor, as shown in the illustrations, is a rotary milking unit or slow motion merry-go-round—a circular platform on which cows are washed and milked at the rate of 240 an hour. The cows step on and off the moving platform at the rate of one every 15 seconds, but there is an intervening ride of $12\frac{1}{2}$ minutes during which the cleaning, foremilk and milking operations are carried on. The operation is continuous until all the cows have been milked.

The motives actuating the development of the rotolactor were the desire to make possible the volume production of clean milk under the most advanced conditions of hygiene and sanitation, and to demonstrate such a system to the end that it might lead to the development of better milk supplies on a wide scale.

In operation the cows move from their living quarters into a separate building and a room devoted only to milking. This room is especially equipped and designed with one principal objective—cleanliness. Walls and floors are tiled and kept clean. The air in the building is filtered and washed so that atmospheric conditions are nearly ideal; there is a complete absence of dust and objectionable odors. There

can be no doubt of the desirability of such a milking room compared to the compromise conditions which confront milk producers in the usual cow stable where there is a continual struggle between factors of stable hygiene, milk hygiene and cow comfort.

The rotolactor provides special means for washing the cows. Except in a few sections of the country where climatic conditions require that cows be stabled only at milking time (and even in these sections only rarely), has it been possible or customary to employ effective quantities of water in preparing cows for milking. On the rotolactor, the cows are subjected to a series of warm spray washes and showers directed particularly against the posterior quarters and udder. These automatic showers are augmented by 2 men with hand hoses, supplying warm water under considerable pressure, who devote their attention to the cleansing of udders and flanks. This is followed by drying of the teats and udders with clean individual towels. Such operations insure the almost complete elimination of foreign materials that might gain entrance to the milk.

Milk goes from the cow's udder to the pyrex glass without being exposed to the air and without any possibility of contamination.

baths as soon as the milk of one cow is discharged from it, giving a clean and practically sterile milking unit, from teat cups to pyrex glass jar, for each cow. Such care of utensils has never before been accomplished and is believed to answer criticisms previously made of the production of high grade milk with machines. The pyrex glass jar also permits inspection of the milk as it comes from the cow and so furnishes an additional check on its quality.

The arrangements for collecting and handling the milk after it leaves the glass jars are such that there is only a momentary exposure

to the atmosphere. The milk is discharged into previously cleaned and sterilized tanks from which it is pumped through sterilized sanitary lines to the coolers, into glass lined mixing tanks, and thence to the automatic bottling and capping machines. Within little more than a minute from the time it leaves the cow, the milk has been cooled, and is maintained at a low temperature until delivered.

With respect to the spread of disease in man through milk, the human element constitutes one of the most important as well as one of the weakest factors. With the rotolactor, human contact even of a remote character is reduced to a minimum. Thus, in milking cows at the rate of 240 an hour, there are only 4 men who are possible contacts: a foremilk, 2 men who attach teat-cups (but who touch the teats scarcely at all), and the attendant of the bottling machine. With these men under effective medical supervision, as well as all others who are even remotely associated with milk production, the possible dangers due to human contacts are as nearly eliminated as is possible, a trend which is now foremost in the preparation of all quality food products.

The production of high grade milk on the volume basis which justifies the construction of such units as the rotolactor makes possible a centralization of control and effective supervision at the source which is not economically feasible with the small scattered units that characterize our present milk supplies.

The construction of the rotolactor building with its visitors' gallery behind glass partitions is such that there can be unlimited observation and study of all milking procedures without the objections which attend the passage of visitors and others through the usual milking stables. With such a machine, backed up by healthy cows and healthy employees, the milk is provided with real protection against the entrance of extraneous bacteria or foreign matter. The degree of purity attained amply justifies the pains taken to accomplish it.

MONTREAL

SOMETHING of the history of Montreal is given in July issue of the JOURNAL, a story full of romance, showing the vision, courage and persistence of the pioneers who founded the city. From the medical and public health standpoint, a full chapter could be written. Without disparagement to the many eminent professional men whose names are associated with its institutions, we may mention two who stood preëminent, William Osler and Wyatt Johnston.

Born in Canada, and always having retained his allegiance to that country and England, Dr. Osler spent much of his professional life in the United States, and while he was first of all a student and teacher of internal medicine, his interests were wide. He was one of the founders of the National Tuberculosis Association. Two years after his graduation from the Toronto Medical School in 1868, he began the work which made him famous in the Montreal General Hospital. In 1872 he was offered the chair of Botany at McGill University, in 1874 became Lecturer in the Institutes of Medicine, and was made Professor of Medicine in 1875. All know of the brilliant record he made. In 1884, he accepted a call to the University of Pennsylvania, leaving there for Baltimore when Johns Hopkins was founded, where he remained until made regius professor at Oxford, England.

The story of Wyatt Johnston is more closely connected with our association, of which he was a member from 1892 until his death, June

19, 1902. His untimely death was a blow to science as well as to our organization. He introduced the Widal Test into America. At our meeting in Buffalo, 1896, he read a paper entitled: "On the Application of the Serum Diagnosis of Typhoid Fever to the Requirements of Public Health Laboratories." Some 27 specimens of blood were sent without histories from Montreal to him at the meeting, and the correct diagnosis made in each case. Following this paper and demonstration, the application of the test rapidly spread over the continent until it became a standard procedure.

Members of our Association will find much of interest in the beautiful city which is to be our host, and we can do nothing better while there than to lay a wreath on the grave of Wyatt Johnston in Mount Royal Cemetery.

SCURVY AND ITS PREVENTION

IN spite of the fact that scurvy was described in 1250,¹ when the first clear accounts of it were given, again in the 15th century when long sea voyages became more frequent, and later in the especially clear account given of the voyage of Vasco di Gama, 1498, during which 55 sailors died, there still seems to be much lack of recognition of the facts, especially those concerning its prevention and cure.

Many writers attribute the discovery of its cause and cure to Capt. Cook, who during his three voyages was very successful in preventing the disease. Such articles as that by Captain Angus² have brought the misunderstanding down to very recent times. This author says, "It was left to the son of a farm labourer, born in 1728, . . . to prove during his three long voyages of exploration how this pest could be completely vanquished." As regards Captain Cook, there seems to be no doubt that before the "Endeavour" sailed, August 26, 1768, the Lord of the Admiralty wrote to him (then Lieutenant) that Dr. David MacBride (1727-1778) in *Experimental Essays on the Scurvy and Other Subjects*, and *An Historical Account of the New Method of Treating the Scurvy at Sea*, had pointed out the means of preventing this scourge. "Fit Experiments" during the voyage according to these methods were ordered, and the Commissioners of the Victualling were directed to put on board the ship a quantity of the antiscorbutics. The Surgeon was to keep an exact journal "describing the several symptoms and relating the progress and effects from time to time, 'which journal is to be transmitted to us at the end of the voyage.'" The lists of foods supplied are extant, in addition to which it is well known that Capt. Cook added wild celery and other wild herbs whenever he was able to collect them. He paid especial attention to per-

sonal cleanliness, the avoidance of wet clothing, and clean quarters, and gave untiring supervision to the health of his men. It seems, then, that credit must be given to Capt. Cook for having been the first to put into effect such measures. He undoubtedly showed, in spite of his lack of education, remarkable judgment, and there is no desire to contradict the accepted fact that his success was due largely to his personal actions. Other voyagers had had antiscorbutics on their ships, yet scurvy occurred. There seems to be just as little doubt that to Dr. David MacBride the suggestions of the causes of scurvy and, as far as Captain Cook is concerned, its prevention were due.

About the same time a number of other English physicians wrote on scurvy, prominent among whom are James Lind (1736-1794) and Thomas Trotter (1785), the latter of whom wrote a "*Medicina nautica*" or a general treatise on the diseases of seamen. However, earlier, John Woodall, born about 1569, was made Surgeon General to the East India Company in 1612, and about this time wrote "*The Surgeon's Mate*." While a surgeon by profession, and having served as a military surgeon in 1589 to the troops sent by Elizabeth to the aid of Henry IV of France, he wrote also a "*Treatise on the Plague*," and another on "*Gangrene and Sphacelus*," all of which were collected into one volume and published in 1639. As far as the present discussion is concerned, his most valuable work was on "the scurvy" in which he described the disease and methods of cure. It is true that he made some mistakes, but he asserted that its principal cause was the long use of salt provisions, coupled with a want of cleanliness and proper change of apparel. He further gave first place in its prevention and treatment to the juice of lemons, but recommended various other acid vegetable juices and fruits. In 1720, Kramer, "*Medicina Castrensis*," spoke positively of the curative properties of green vegetables, oranges, lemons, and citrons, and told how to preserve the pulp of the citrous fruits for prolonged use.

Writing in 1780, John Aiken¹ refers to "the very ingenious Dr. MacBride," and states that he particularly commended the treatise of Dr. Woodall and quoted from it. He further expressed his surprise that few of the writers of the time had mentioned him or his work.

". . . I hold strongly with the statement that it is a sign of a dry age when the great men of the past are held in light esteem."

PRELIMINARY PROGRAM OF THE SIXTIETH ANNUAL MEETING

AMERICAN PUBLIC HEALTH ASSOCIATION

Montreal, Quebec, September 14-17, 1931

THE Annual Meeting Program Committee presents herewith the preliminary program of the scientific sessions of the American Public Health Association and information concerning meetings of related organizations held in connection with the Sixtieth Annual Meeting.

Scientific trips are announced elsewhere in this *Journal*. Entertainment plans, always important features of the Annual Meeting, are not listed at this time. The next issue of the *Journal* will provide details about them.

The 3-day post-convention trip to Quebec and the Saguenay River has been announced to members in correspondence and will be referred to again in a later *Journal*.

Since the following program cannot be considered definite in every respect now, delegates are urged to consult the final program, available at the Registration Desk in the Windsor Hotel at the time of the meeting. Exact hours and places will be announced therein.

GENERAL SESSIONS

First Session—Monday Evening

Invocation. MGR. GEORGES GAUTHIER, Archbishop Coadjutor of Montreal and Chancellor of the University of Montreal.

RT. REVEREND J. C. FARTHING, Anglican Bishop of Montreal.

Addresses of Welcome.

S. BOUCHER, M.D., D.P.H., Director, Department of Health, and Chairman of the Local Committee, Montreal, Que.

HIS WORSHIP CAMILLIEN HOUDE, Mayor of Montreal.

HONORABLE ATHANASE DAVID, Provincial Secretary, Quebec, Que.

HONORABLE MURRAY MACLAREN, Minister of Pensions and National Health, Ottawa, Ont.

E. W. BEATTY, LL.D., Chancellor, McGill University, Montreal, Que.

JOHN A. AMYOT, M.D., Deputy Minister of Health, Ottawa, Ont.

ALPHONSE LESSARD, M.D., Director, Provincial Bureau of Health, Quebec, Que.

Address of the President of the American Public Health Association. HUGH S. CUMMING, M.D., Surgeon-General, U. S. Public Health Service, Washington, D. C.

Reception and Dancing.

*Second Session—Luncheon—Thursday***Reports of the Four Standing Committees of the Association:**

Committee on Administrative Practice. *Chairman*, C.-E. A. WINSLOW, DR.P.H., Yale University, New Haven, Conn.

Committee on Fellowship and Membership. *Chairman*, SALLY LUCAS JEAN, New York, N. Y.

Committee on Meetings and Publications. *Chairman*, C. C. YOUNG, D.P.H., Director of Laboratories, State Department of Health, Lansing, Mich.

Committee on Research and Standards. *Chairman*, ABEL WOLMAN, Chief Engineer, State Department of Health, Baltimore, Md.

Third Session—Banquet—Thursday Evening

The Duty of the State in the Matter of Health. HONORABLE ATJIANASE DAVID, Provincial Secretary, Quebec, Que.

Announcement of Awards.

Dancing.

SPECIAL SESSIONS**SYMPOSIUM ON TOXOID IMMUNIZATION***Tuesday Morning*

Presiding: C. C. YOUNG, D.P.H., Director of Laboratories, State Department of Health, Lansing, Mich.

Toxoid versus Toxin-antitoxin in Immunization of Children under Various Conditions. WILLIAM H. PARK, M.D., and MAY C. SCHROEDER, M.D., Bureau of Laboratories, Department of Health, New York, N. Y.

The Degree of Immunization in the Guinea Pig from the Injection of Diphtheria Toxoid, (a) of Different Strengths, (b) at Various Intervals, and (c) of Treated Toxoids. OLGA R. POVITZKY, M.D., Bureau of Laboratories, Department of Health, New York, N. Y.

Discussion. P. J. MOLONEY, PH.D., Connaught Laboratories, University of Toronto, Toronto, Ont.

Advantages of Toxoid in Diphtheria Prophylaxis. W. T. HARRISON, M.D., National Institute of Health, Washington, D. C.

Experiences with Toxoid in Toledo. JOHN L. LAVAN, M.D., Commissioner of Health, Toledo, O.

Experiences with Toxoid in Canada. R. D. DEFRIES, M.D., D. T. FRASER, D.P.H., NEIL E. MCKINNON, M.B., and P. J. MOLONEY, PH.D., Connaught Laboratories, University of Toronto, Toronto, Ont.

The Inunction Method of Immunization Against Diphtheria. C. C. YOUNG, D.P.H., Director of Laboratories, C. D. BARRETT, M.D., Epidemiologist, State Department of Health, Lansing, Mich., and MORTIMER BYE, William S. Merrell Company, Cincinnati, O.

Concentrated Toxoid. W. E. BUNNEY, PH.D., State Department of Health, Lansing, Mich.

SYMPOSIUM ON RURAL SANITATION

Wednesday Morning

Presiding: JOHN A. FERRELL, M.D., DR.P.H., Associate Director, International Health Division, Rockefeller Foundation, New York, N. Y.
Rural or County Health Service.

Viewed from National Standpoint: Importance, Policies, Support. JOHN A. AMYOT, M.D., Deputy Minister of Health, Ottawa, Ont., RAFAEL SILVA, M.D., Director of Public Health Department of Mexico, Mexico City, Mex., and HUGH S. CUMMING, M.D., Surgeon-General, U. S. Public Health Service, Washington, D. C.

Viewed from Provincial and State Standpoints: Organization, Financing, Program, Personnel. ALPHONSE LESSARD, M.D., Director, Provincial Bureau of Health, Quebec, Que., A. T. MCCORMACK, M.D., State Health Officer, Louisville, Ky., and F. J. UNDERWOOD, M.D., State Health Officer, Jackson, Miss.

Viewed from the County Standpoint: Organization, Activities, Financing, Personnel. J. E. SYLVESTRE, M.D., Health Officer, Levis County, Que., R. M. ATWATER, M.D., DR.P.H., Health Officer, Cattaraugus County, Olean, N. Y., J. B. BLACK, M.D., County Health Officer, Rutherford County, Murfreesboro, Tenn., and W. A. MCINTOSH, M.D., State Department of Health, Lansing, Mich.

Discussion. W. F. DRAPER, M.D., Assistant Surgeon-General, U. S. Public Health Service, Washington, D. C., E. L. BISHOP, M.D., State Commissioner of Health, Nashville, Tenn., THOMAS PARRAN, JR., M.D., State Commissioner of Health, Albany, N. Y., and ALLEN W. FREEMAN, M.D., Professor of Public Health Administration, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

SYMPOSIUM ON HEALTH FACTS AND HEALTH EDUCATION

Thursday Morning

Presiding: CHARLES F. WILINSKY, M.D., Deputy Commissioner, Child Hygiene Division, Department of Health, Boston, Mass.

What to Tell (Health Facts). DONALD B. ARMSTRONG, M.D., Sc.D., Fourth Vice-President, Welfare Division, Metropolitan Life Insurance Company, New York, N. Y.

Motivating Men. EDWARD L. BERNAYS, Counsel on Public Relations, New York, N. Y.

What Is Health News? GEORGE F. WRIGHT, Editor, *Montreal Daily Star*, Montreal, Que.

Cholera Prevention Parade in Shanghai. *Motion Picture.* W. W. PETER, M.D., DR.P.H., Director, Health Service, Cleanliness Institute, New York, N. Y.

JOINT SESSIONS

PUBLIC HEALTH EDUCATION AND PUBLIC HEALTH
NURSING SECTIONS*Monday Morning*

HEALTH EDUCATION IN HIGH SCHOOL

What Constitutes Health Education in the High School? IAGO
GALDSTON, M.D., Medical Information Bureau, New York Academy of
Medicine, New York, N. Y.

Health—Where Can It Be Taught? PROFESSOR CLAIR E. TURNER,
Massachusetts Institute of Technology, Cambridge, Mass.

How It Is Being Taught by a Public Health Nurse. ETTA A.
CREECH, R.N., Teacher of Hygiene, Heights High School, Cleveland
Heights, O.

CHILD HYGIENE AND PUBLIC HEALTH NURSING SECTIONS

Monday Afternoon

Presiding: C. M. HINCKS, M.D., Director, Canadian National Committee
for Mental Hygiene, and General Director, United States National
Committee for Mental Hygiene, Toronto, Ont.

SYMPOSIUM ON MENTAL HYGIENE

When Is a Community Ready for a Mental Hygiene Clinic Service?

Mental Hygiene Concepts. GEORGE K. PRATT, M.D., Associate
Medical Officer, National Committee for Mental Hygiene, New York,
N. Y.

Minimum Community Provisions Necessary in Related Fields of
Endeavor.

a. Education. No author.

b. Social Work. C. C. CARSTENS, PH.D., Executive Director,
Child Welfare League of America, New York, N. Y.

c. Medical. No author.

d. Public Health Nursing. KATHARINE TUCKER, R.N., General
Director, National Organization for Public Health Nursing,
New York, N. Y.

A Suggested Community Program. GEORGE S. STEVENSON, M.D.,
Field Consultant, National Committee for Mental Hygiene, New
York, N. Y.

Discussion. STANLEY H. OSBORN, M.D., State Commissioner of Health,
Hartford, Conn.

What Can a Community Do When It Is Not Yet Ready to Estab-
lish a Mental Hygiene Clinic?

Suggestions for Local Consideration. HERMAN G. WEISKOTTEN, M.D., Dean, College of Medicine, Syracuse University, Syracuse, N. Y.

Discussion. EFFIE J. TAYLOR, Professor of Nursing, Yale University School of Nursing, New Haven, Conn.

HEALTH OFFICERS AND EPIDEMIOLOGY SECTIONS

Thursday Morning

Control of Syphilis from the Epidemiologist's Point of View. THOMAS PARRAN, JR., M.D., State Commissioner of Health, Albany, N. Y.

Syphilis in a Rural Colored Population in Tennessee. E. L. BISHOP, M.D., State Commissioner of Health, and associates of the State Department of Health, Nashville, Tenn.

Practicability of Epidemiological Methods in the Control of Syphilis. WILLIAM L. MUNSON, M.D., District Health Officer, Granville, N. Y.

Control of Syphilis from the Health Officer's Viewpoint. N. A. NELSON, State Department of Health, Boston, Mass.

LABORATORY AND FOOD, DRUGS AND NUTRITION SECTIONS

Wednesday Morning

Types of Streptococci in Infected Udders That Show No Clinical Evidence of Mastitis. G. J. HUCKER, PH.D., Chief in Research, New York State Agricultural Experiment Station, Geneva, N. Y.

Health Examinations of Milk Handlers. MILLARD KNOWLTON, M.D., and HARRIET BIXBY, State Department of Health, Hartford, Conn.

Bacteriological Studies of an Epidemic of Septic Sore Throat. W. D. FROST, DR.P.H., MILDRED GUMM and W. D. STOVALL, M.D., Laboratories of Agricultural Bacteriology and the Hygienic Laboratory, University of Wisconsin, Madison, Wis.

Montreal Milk Epidemic of 1927. H. D. PEASE, M.D., Pease Laboratories, New York, N. Y.

Judging the Efficiency of the Enforcement of Sanitary Milk Regulations. J. D. BREW, PH.D., Milk Specialist, Bureau of Milk Sanitation, State Department of Health, Albany, N. Y.

PUBLIC HEALTH ENGINEERING AND FOOD, DRUGS AND
NUTRITION SECTIONS*Wednesday Afternoon*

Report of the Committee on Milk and Dairy Products. (Food, Drugs and Nutrition Section.) *Chairman*, WILLIAM B. PALMER, Executive Officer, Milk Inspection Association of the Oranges, Orange, N. J.

Report of the Committee on Milk Supply. (Public Health Engineering Section.) *Chairman*, C. A. HOLMQUIST, Director, Division of Sanitation, State Department of Health, Albany, N. Y.

Milk Sanitation in Canada. R. H. MURRAY, Director, Division of Sanitation, Department of Public Health, Regina, Sask.

Discussion. L. C. FRANK, Office of Milk Investigations, U. S. Public Health Service, Washington, D. C.

Sanitary Regulation of Canneries. E. L. FILBY, Chief Engineer, Bureau of Engineering, State Board of Health, Jacksonville, Fla.

Ice Cream Sanitation and Control. F. W. FABIAN, PH.D., Associate Professor of Bacteriology, Michigan State College, East Lansing, Mich.

Import Milk Control Methods. H. B. SWITZER, Chief, Rouses Point Import Milk Inspection Station, U. S. Department of Agriculture, Rouses Point, N. Y.

VITAL STATISTICS AND EPIDEMIOLOGY SECTIONS

Wednesday Afternoon

Tuberculosis in the Negro in Rural Tennessee. E. L. BISHOP, M.D., State Commissioner of Health, and associates of the State Department of Health, Nashville, Tenn.

The Incidence of Tuberculosis in the Industrial Population. LOUIS I. DUBLIN, PH.D., Statistician, Metropolitan Life Insurance Company, New York, N. Y.

Tuberculosis in Young Females. W. J. V. DEACON, M.D., Director, Bureau of Records and Statistics, Department of Health, Lansing, Mich.

Trend of Tuberculosis in Massachusetts as Illustrated by the Three Dimensional Graph. G. SMILLIE, M.D., and W. F. WELLS, School of Public Health, Harvard University, Boston, Mass.

SECTION SESSIONS

LABORATORY

First Session—Monday Morning

Report of the Committee on Standard Methods. (Recommendations for the Seventh Edition of *Standard Methods of Water Analysis*.) *Secretary*, JOHN F. NORTON, PH.D., Department of Health Laboratories, Detroit, Mich.

Laboratory Methods Used in the Official Control of Milk Supplies.

ROBERT S. BREED, PH.D., and CARL S. PETERSON, PH.D., New York State Agricultural Experiment Station, Geneva, N. Y.

Results on Cold Clarification with Reference to Bacterial and Chemical Changes in Milk. N. E. LAZARUS, President, Lacteal Analytical Laboratories, Buffalo, N. Y.

The Interpretation of Direct Colon-Aerogenes Counts in Well Waters. FRED O. TONNEY, M.D., and RALPH E. NOBLE, Department of Health, Chicago, Ill.

Some Experimental Evidence Concerning the Interpretation of Laboratory Findings in Rural Water Supplies of the Appalachian Area. EDMUND K. KLINE, DR.P.H., Cattaraugus County Department of Health Laboratory, Olean, N. Y.

Monilias, Yeasts and Cryptococci, Their Pathogenicity, Classification and Identification. RHODA W. BENHAM, PH.D., Laboratory for Medical Mycology of the Department of Dermatology, College of Physicians and Surgeons, Columbia University, New York, N. Y.

Minimal "Chlorine Death Points" of Pathogenic Fungi. GERALD HOEFT and JOHN L. WHITE, M.D., Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

The Identification of Certain Yeast-like Fungi Pathogenic for Man. W. D. STOVALL, M.D., and ANNA BUBOLZ, State Laboratory of Hygiene, Madison, Wis.

Some Factors Influencing the Growth and Morphology of *Corynebacterium Diphtheriae* in Throat Cultures. ROSS L. LAYBOURN, Laboratories of State Board of Health, Jefferson City, Mo.

The Preparation of Stabilized Schick Test Toxin. P. J. MOLONEY, PH.D., and E. M. TAYLOR, PH.D., Connaught Laboratories, University of Toronto, Toronto, Ont.

Second Session—Thursday Afternoon

Observations on the Etiology of Epidemic Influenza. I. S. FALK, PH.D., Washington, D. C.

The Cancer Situation as It Affects the Public Health Laboratory, with Demonstration of Actual Living and Growing Human Cancer Cells. JOSEPH COLT BLOODGOOD, M.D., Clinical Professor of Surgery, Johns Hopkins University, Baltimore, Md.

The Coli-Aerogenes Determination in Pasteurization Control. M. H. MCCRADY, Chief of Laboratories, Provincial Bureau of Health, Montreal, Que.

Eberthella Paratyphosa as a Causative Agent of Diarrheal Disease in Connecticut. HENRY WELCH, PH.D., and FRIEND LEE MICKLE, Bureau of Laboratories, State Department of Health, Hartford, Conn.

Correlated Carbohydrate and Serologic Variations in the Morgan's Bacillus Group. L. C. HAVENS, M.D., and ANNE G. IRWIN, State Board of Health, Montgomery, Ala.

Studies on the Self-Disinfecting Power of the Skin. JOHN F. NORTON, PH.D., and MARGUERITE F. NOVY, Department of Health Laboratories, Detroit, Mich.

Food Poisoning Due to Toxic Substances Formed by Strains of the Cloacae-Aerogenes Group. RUTH GILBERT, M.D., MARION B. COLEMAN and ALICE B. LAVIANO, Division of Laboratories and Research, State Department of Health, Albany, N. Y.

Action of Some Common Disinfectants on Phagocytes in Vivo. E. MEGRAIL, M.D., and D. J. SHAW, Department of Hygiene and Bacteriology, School of Medicine, Western Reserve University, Cleveland, O.

The Effect of Scarlatinal Toxin on Chinchilla Rabbits. FRIEDA H. FRASER, Research Associate, Connaught Laboratories, University of Toronto, Toronto, Ont.

(For joint session see page 906.)

HEALTH OFFICERS

First Session—Monday Afternoon

Evaluation of Diphtheria Prevention Work. EDWARD S. GODFREY, JR., M.D., State Department of Health, Albany, N. Y.

Discussion. W. W. BAUER, M.D., Commissioner of Health, Racine, Wis.

Observation or Control of Communicable Diseases. HOWARD A. STREETER, M.D., City Isolation Hospital, Manchester, N. H.

Discussion. JOSEPH SMITH, M.D., Department of Health, Providence, R. I.

Tuberculosis Control Without Hospitalization. C. H. KIBBEY, M.D., Director of Sanitation, Tennessee Coal, Iron and Railroad Company, Fairfield, Ala.

Discussion. M. W. GLASGOW, M.D., Fairfield, Ala.

What the Nurse Expects (or Would Like to Expect) of Her Chief, the Health Officer. AGNES J. MARTIN, R.N., Director of Nurses, Department of Health, Syracuse, N. Y.

Discussion. H. J. KNAPP, M.D., Health Officer, Cleveland, O.

Second Session—Wednesday Afternoon

Discussion of the Recommendations of the Committee on Business Management.* *Chairman,* GEORGE C. RUHLAND, M.D., Commissioner of Health, Syracuse, N. Y.

* Mimeographed copies of the Report will be distributed to members of the Section.

Evolution of Public Health Administration. PETER H. BRYCE, M.D.,
Ottawa, Ont.

What Should a Health Department Be Doing About Cancer?
CLARENCE C. LITTLE, Sc.D., Managing Director, American Society for
the Control of Cancer, New York, N. Y.

Discussion. GEORGE H. BIGELOW, M.D., State Health Commissioner,
Boston, Mass.

What Should a Health Department Be Doing About Accidental
Deaths? LOUIS I. DUBLIN, PH.D., Statistician, Metropolitan Life In-
surance Company, New York, N. Y.

What Should a Health Department Be Doing About Mental Hy-
giene? EDGAR VAN NORMAN EMLERY, M.D., Yale Medical School, New
Haven, Conn.

Discussion. A. GRANT FLEMING, M.D., Professor of Public Health and
Preventive Medicine, McGill University, Montreal, Que.

Joint Dinner—Wednesday

Health Officers Section.

Child Hygiene Section.

American Association of School Physicians.

International Society of Medical Health Officers.

(For joint session see page 906.)

VITAL STATISTICS

First Session—Monday Morning

Report of the Committee on Registration Affairs. *Chairman*, T. F.
MURPHY, M.D., Chief Statistician for Vital Statistics, Bureau of the
Census, Washington, D. C.

Seasonal Incidence of Whooping Cough in the United States.
GAIUS E. HARMON, M.D., Department of Hygiene and Bacteriology,
School of Medicine, Western Reserve University, Cleveland, O.

Have We Still a Smallpox Menace? GEORGE H. VAN BUREN, Super-
visor, Statistical Bureau, Metropolitan Life Insurance Company, New
York, N. Y.

Report of the Committee on Proper Allocation of Records. *Chair-
man*, J. V. DEPORTE, PH.D., Director, Division of Vital Statistics,
State Department of Health, Albany, N. Y.

Vital Statistics in the Development of Neighborhood Health Cen-
ters in New York City. GODIAS J. DROLET, Consulting Statistician,
Committee on Neighborhood Health Development, and LOUIS WEINER,
Vital Statistician, Department of Health, New York, N. Y.

Discussion. CHARLES F. WILINSKY, M.D., Deputy Commissioner, Child
Hygiene Division, Department of Health, Boston, Mass.

Basic Records for Use in a County Health Department. JOHN COLLINSON, M.D., DR.P.H., Chief, Bureau of Vital Statistics, State Department of Health, Baltimore, Md.

Report of the Committee on Coöperation with National Safety Council in Preparing Forms for Additional Information Regarding Accidents. *Acting Chairman*, E. W. KOPF, Metropolitan Life Insurance Company, New York, N. Y.

Second Session—Tuesday Afternoon

SYMPOSIUM ON VITAL STATISTICS REGISTRATION PROBLEMS

Third Session—Thursday Morning

Morbidity from Heart Disease in the State of New York (Exclusive of New York City). J. V. DEPORTE, PH.D., Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

Report of the Committee on Registration of Births of Illegitimate and Adopted Children. *Acting Chairman*, SHELDON L. HOWARD, State Registrar of Vital Statistics, State Department of Health, Springfield, Ill.

Report of the Committee on Public Health Climatology. *Chairman*, E. W. KOPF, Metropolitan Life Insurance Company, New York, N. Y.

A Study of Heart Disease in Continuation School Boys, Statistics, Comparative Statistics, Clinical Signs, etc. JEROME MEYERS, M.D., Department of Health, New York, N. Y.

Discussion. ELWOOD S. MORTON, M.D., Chief, Bureau of Industrial and Adult Hygiene, Department of Health, New York, N. Y.

An Analysis of the Birth Statistics of the State of New York for a Period of Ten Years. ELIZABETH PARKHURST, State Department of Health, Albany, N. Y.

Report of the Committee on Forms and Methods of Statistical Practice. *Chairman*, A. W. HEDRICH, Sc.D., Associate in Biostatistics, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

A Study in Maternal Mortality. E. S. MACPHAIL, Chief, Division of Census and Vital Statistics, Dominion Bureau of Statistics, Ottawa, Ont.

Mortality by Census Tracts in Cincinnati for 1930. FLOYD P. ALLEN, M.D., Secretary, The Heart Council of Greater Cincinnati, Cincinnati, O.

(For joint session see page 907.)

PUBLIC HEALTH ENGINEERING

First Session—Tuesday Morning

The Cost of Sanitary Surveys of Streams. W. L. STEVENSON, Chief Engineer, State Department of Health, Harrisburg, Pa.

Discussion.

Report of the Committee on Waterways Pollution. *Chairman*, EARNEST BOYCE, Director and Chief Engineer, Division of Sanitation, State Board of Health, Lawrence, Kans.

The Sanitary Inspector in Rural Sanitation. H. W. VAN HOVENBERG, Sanitary Engineer, St. Louis Southwestern Railway Company, Texarkana, Tex.

Discussion. W. F. DRAPER, M.D., Assistant Surgeon-General, U. S. Public Health Service, Washington, D. C.

Report of the Committee on Rural Sanitation. *Chairman*, H. B. HOMMON, Sanitary Engineer, U. S. Public Health Service, San Francisco, Calif. (To be presented by title only.)

Town Planning and Housing in Canada. F. A. DALLYN, Consulting Public Health and Municipal Engineer, Toronto, Ont.

Discussion.

Report of the Committee on Environmental Sanitation. *Chairman*, G. W. PUTNAM, Director of Research, Creamery Package Manufacturing Company, Chicago, Ill. (To be presented by title only.)

Modern Housing and Sanitation. J. H. FINK, Secretary, Housing Committee, Bureau of Charities, Brooklyn, N. Y.

Joint Dinner—Wednesday

Public Health Engineering Section and Conference of State Sanitary Engineers. Annual Engineers' Stag Dinner Party.

Second Session—Thursday Morning

SYMPOSIUM ON DROUGHT

Drought and Health. No author.

Effect of Drought on Water Supplies. E. S. TISDALE, Director, Division of Sanitary Engineering, State Department of Health, Charleston, W. Va.

Discussion. H. E. MOSES, Assistant Chief Engineer, Department of Health, Harrisburg, Pa.

The Effect of Sewage on Water Supplies During Times of Drought. No author.

An Epidemiological Study of Water-Borne Enteritis. M. V. VELDEE, M.D., Surgeon, U. S. Public Health Service, Washington, D. C.

Discussion. LLOYD ARNOLD, M.D., Department of Pathology and Bacteriology, College of Medicine, University of Illinois, Chicago, Ill.

Teaching Engineers Public Health. PROFESSOR SAMUEL C. PRESCOTT, Department of Biology and Public Health, Massachusetts Institute of Technology, Cambridge, Mass.

Discussion. PROFESSOR E. B. PHELPS, College of Physicians and Surgeons, Columbia University, New York, N. Y.

Report of the Committee on Education and Training. *Chairman*, ABEL WOLMAN, Chief Engineer, State Department of Health, Baltimore, Md.

Third Session—Thursday Afternoon

Contamination of Water Mains by Jute Packing. C. H. SPAULDING, Superintendent of Water Purification, Springfield, Ill.

Report of the Committee on Water Supply. *Chairman*, J. R. BAYLIS, Engineer, Bureau of Engineering, Department of Public Works, Chicago, Ill.

Report of the Sub-Committee on Ground Water of the Committee on Water Supply. *Sub-Chairman*, W. S. JOHNSON, Chief Public Health Engineer, State Board of Health, Jefferson City, Mo. (To be presented by title only.)

The Montreal Water Supply. C. J. DES BAILLETS, Chief Engineer, Montreal Water Board, Montreal, Que.

Report of the Committee on Disaster Relief. *Chairman*, E. L. FILBY, Chief Engineer, State Board of Health, Jacksonville, Fla. (To be presented by title only.)

Report of the Committee on Industrial Plant Sanitation. *Chairman*, F. GARDNER LEGG, JR., Sanitary Engineer, Department of Health, Detroit, Mich. (To be presented by title only.)

Report of the Committee on Record Forms. *Chairman*, I. W. MENDELSON, Sanitary Engineer, Washington, D. C.

Discussion. JOEL I. CONNOLLY, Chief Sanitary Engineer, Department of Health, Chicago, Ill.

Report of the Committee on Sewage Disposal. *Chairman*, LANGDON PEARSE, Sanitary Engineer, Sanitary District of Chicago, Chicago, Ill.

Section Business.

(For joint session see page 907.)

INDUSTRIAL HYGIENE

First Session—Monday Afternoon

Presiding: L. R. THOMPSON, M.D., *Chairman*, Industrial Hygiene Section.

Trends and Opportunities in Industrial Hygiene. L. R. THOMPSON, M.D., Assistant Surgeon General, U. S. Public Health Service, Washington, D. C.

Endocrin Dysfunctions Among Industrial Workers. VOLNEY S. CHENEY, M.D., Armour and Company, Chicago, Ill.

Discussion.

Relative Pneumonia Fatality Among Surface Workers and Miners.
C. H. KIBBEY, M.D., Director of Sanitation, Tennessee Coal, Iron &
Railroad Company, Fairfield, Ala.

Discussion.

Prevalence of Respiratory Diseases Among Employees, with Refer-
ence to Age, Sex and Occupation. MICHAEL LAKE, M.D., R. H.
Macy and Company, New York, N. Y.

Discussion.

Section Business.

INDUSTRIAL HYGIENE SECTION COMMITTEE REPORTS

The following Committees will make reports to the Section Council.
Mimeographed copies of these reports will be available to all those in
attendance.

Committee on Standard Practices in the Problem of Compensation
of Occupational Diseases. *Chairman*, HENRY H. KESSLER, M.D.,
State Department of Labor, Newark, N. J.

Committee on Lead Poisoning. *Chairman*, EMERY R. HAYHURST,
M.D., State Department of Health, Columbus, O.

Committee on Pneumoconiosis. *Chairman*, R. R. SAYERS, M.D.,
U. S. Bureau of Mines, Washington, D. C.

Second Session—Tuesday Morning

The Toxicity of Methyl Alcohol. HENRY FIELD SMYTH, M.D., Uni-
versity of Pennsylvania, Philadelphia, Pa.

Discussion.

Silicosis in the Abrasive Powder Industry. HENRY H. KESSLER,
M.D., State Department of Labor, Newark, N. J.

Discussion.

The Advance Program of Industrial Hygiene in New York State.
GEORGE M. PRICE, M.D., New York State Department of Health, New
York, N. Y.

Discussion.

Old Age Security Work. LUTHER GULICK, PH.D., Director, National
Institute of Public Administration, New York, N. Y.

Discussion.

Section Council Meeting.

Dinner in honor of Dr. Alice Hamilton—Tuesday

Presiding: ANTHONY J. LANZA, M.D., Medical Consultant, General Motors
Corporation, New York, N. Y.

Alice Hamilton the Industrial Hygienist. C.-E. A. WINSLOW,
DR.P.H., Yale University, New Haven, Conn.

My Years in Industrial Hygiene. ALICE HAMILTON, M.D., Assistant Professor, Industrial Medicine, Harvard School of Public Health, Boston, Mass.

Third Session—Wednesday Morning

Work Environment as a Factor in General Health of Workers. BERNARD J. NEWMAN, Managing Director, Philadelphia Housing Association, Philadelphia, Pa.

Discussion.

Medical Services of the Bell Telephone Company of Canada. A. R. PENNOYER, M.D., Medical Director, The Bell Telephone Company of Canada, Montreal, Que.

Discussion.

Compensation for Silicosis. J. G. CUNNINGHAM, M.B., Director, Division of Industrial Hygiene, Department of Health, Toronto, Ont.

Discussion. T. N. DEAN, Statistician, Workman's Compensation Board, Toronto, Ont.

Physical Impairment Among One Thousand Negro Workers. FLOYD P. ALLEN, M.D., Secretary, The Heart Council of Greater Cincinnati, Cincinnati, O.

Discussion.

Section Council Meeting.

FOOD, DRUGS AND NUTRITION

First Session—Monday Afternoon

A Basis of Rationing Federal Prisoners. PAUL E. HOWE, PH.D., Senior Biological Chemist in charge Nutrition Investigations, Bureau of Animal Industry, U. S. Department of Agriculture, and A. H. MACCORMICK, Assistant Director, Bureau of Prisons, U. S. Department of Justice, Washington, D. C.

Public Health Aspects of Frozen Foods. CARL R. FELLERS, PH.D., Research Professor, Horticultural Manufactures, Massachusetts State College, Amherst, Mass.

A Health Aspect of Frozen Vegetables. L. H. JAMES, PH.D., and R. P. STRAKA, Food Research Division, Bureau of Chemistry and Soils, U. S. Department of Agriculture, Washington, D. C.

Report of Committee on Fish and Shell Fish. *Chairman,* A. C. HUNTER, PH.D., In charge, Bacteriological Unit, Food Control Laboratory, Food and Drug Administration, U. S. Department of Agriculture, Washington, D. C.

Are Chromates Poisonous? M. J. PRUCHA, PH.D., Professor of Dairy Bacteriology, Agricultural Experiment Station, University of Illinois, Urbana, Ill.

Report of Committee on Cereals and Their Products. *Chairman,* F. C. BLANCK, PH.D., Food Research Division, U. S. Bureau of Chemistry and Soils, Washington, D. C.

Second Session—Tuesday Morning

Report of the Committee on Sanitary Regulations of Public Eating Places. *Chairman*, J. H. SHRADER, PH.D., Research Laboratories, National Dairy Products Corporation, Baltimore, Md.

The Principles and Practice of Health through Anabolic Nutrition. FRANCIS LOWELL BURNETT, M.D., Massachusetts General and Peter Brigham Hospital, Boston, Mass.

Report of the Committee on Nutritional Problems. *Chairman*, PROFESSOR HENRY C. SHERMAN, Department of Chemistry, Columbia University, New York, N. Y.

The Effect of Lead Arsenate Spray on the Composition and Vitamin Content of Oranges. E. M. NELSON, PH.D., and H. H. MORTEN, Bureau of Chemistry and Soils, U. S. Department of Agriculture, Washington, D. C.

Report of the Committee on Meat and Meat Products. *Chairman*, PAUL E. HOWE, PH.D., Senior Biological Chemist in charge Nutrition Investigations, Bureau of Animal Industry, U. S. Department of Agriculture, Washington, D. C.

Report of the Committee on Fruits and Vegetables. *Chairman*, WALTER H. EDDY, PH.D., Teachers College, Columbia University, New York, N. Y.

Luncheon Session—Tuesday

Section Business.

(For joint sessions see pages 906 and 907.)

CHILD HYGIENE

First Session—Tuesday Afternoon

PUBLIC HEALTH AIMS AND PROFESSIONAL SERVICES DURING INFANCY, PRESCHOOL AND SCHOOL AGES

Medical. HELEN MACMURCHY, M.D., Chief, Division of Child Welfare, Department of Pensions and National Health, Ottawa, Ont.

Nursing. HORTENSE HILBERT, R.N., Staff Associate on Nursing, American Child Health Association, New York, N. Y.

Dental. ALFRED WALKER, D.D.S., The Murry and Leonie Guggenheim Dental Clinic, New York, N. Y.

Discussion.

ADMINISTRATION—ROUND TABLE

Rural and Town.

Administrator. ANNA RUDE, M.D., Director, Bureau of Maternal and Child Hygiene, Los Angeles County Health Department, Los Angeles, Calif.

Pediatrician. J. H. MASON KNOX, M.D., Chief, Bureau of Child Hygiene, State Department of Health, Baltimore, Md.

Nurse. ANNA HEISLER, R.N., Professor of Public Health Nursing, Washington University, St. Louis, Mo.

Dentist. HARRY S. THOMSON, D.M.D., Field Secretary, Canadian Dental Hygiene Council, Toronto, Ont.

Medium City.

Administrator. GEORGE C. RUHLAND, M.D., Commissioner of Health, Syracuse, N. Y.

Pediatrician. W. W. BAUER, M.D., Commissioner of Health, Racine, Wis.

Dentist. GEORGE H. WANDEL, D.D.S., Supervisor, Bureau of Dental Health Education, American Dental Association, Chicago, Ill.

Large City.

Administrator. HERMAN N. BUNDESEN, M.D., Commissioner of Health, Chicago, Ill.

Nurse. ESTHER M. BEITH, Executive Director, Child Welfare Association, Montreal, Que.

Specialists:

Nutrition. LUCY H. GILLET, Superintendent, Nutrition Bureau, Association for Improving the Condition of the Poor, New York, N. Y.

Recreation. A. S. LAMB, M.D., Director, Department of Physical Education, McGill University, Montreal, Que.

Luncheon Session—Wednesday

Second Session—Thursday Afternoon

EDUCATION AND TRAINING OF PERSONNEL FOR CHILD HEALTH WORK

What Should Be Taught and How.

General Considerations Including Personal Qualifications. ELIZABETH M. GARDINER, M.D., Director, Division of Maternity and Child Hygiene, State Department of Health, Albany, N. Y.

Administrative. JOHN A. FERRELL, M.D., D.P.H., Associate Director, International Health Division, Rockefeller Foundation, New York, N. Y.

Medical. J. H. MASON KNOX, M.D., Chief, Bureau of Child Hygiene, State Department of Health, Baltimore, Md.

Nursing. HELEN CHESLEY PECK, R.N., Executive Secretary, Infant Welfare Society, Minneapolis, Minn.

Dental. No author.

Social Aspects. No author.

Discussion.

What Is Being Taught and Where (Survey).

Graduate Courses Available (Public Health Schools).

For Physicians. Theory and Practice. No author.

For Nurses. Theory and Practice. MARION G. HOWELL, R.N., Director, School of Applied Social Sciences, Western Reserve University, Cleveland, O.

Staff Education (Survey).

For Physicians. Theory and Practice. WALTER S. CORNELL, M.D., Director, Medical Inspection of Public Schools, Philadelphia, Pa.

For Nurses. Theory and Practice. ELIZABETH FOX, R.N., Director, Visiting Nurse Association, New Haven, Conn.

(For joint session see page 905. For joint dinner see page 910.)

PUBLIC HEALTH EDUCATION

First Session—Tuesday Morning

SCIENTIFIC FACTS FOR PUBLIC CONSUMPTION

Facts from Technical Sections.

Epidemiology. EDWARD S. GODFREY, JR., M.D., Director, Division of Communicable Diseases, State Department of Health, Albany, N. Y.

Child Hygiene. RICHARD A. BOLT, M.D., Director, Cleveland Child Health Association, Cleveland, O.

Food, Drugs and Nutrition. JAMES A. TOBEY, DR.P.H., Director, Health Service, The Borden Company, New York, N. Y.

How May These Facts Be Given to the Public? RAYMOND S. PATTERSON, PH.D., Life Conservation Service, John Hancock Mutual Life Insurance Company, Boston, Mass.

- Dinner Session—Tuesday

Closed session—for members and fellows of the Section only
Section Business.

Second Session—Wednesday Morning

NEWER TOOLS FOR DRAMATIZING HEALTH EDUCATION TO THE GENERAL PUBLIC

New Opportunities in the Use of the Motion Picture. H. E. KLEIN-SCHMIDT, M.D., Director, Health Education Service, National Tuberculosis Association, New York, N. Y.

Radio Broadcasting in Health Education. ELIZABETH C. NICKERSON, State Department of Health, Hartford, Conn.

Mass Health Education in America and Europe. HOMER N. CALVER, New York, N. Y., and BERTRAND BROWN, Director, Division of Publications, Milbank Memorial Fund, New York, N. Y.

Luncheon Session—Wednesday

What's On Your Mind? EVART G. ROUTZAHN, Associate Director, Surveys and Exhibits Department, Russell Sage Foundation, New York, N. Y.

Questions and Answers About Popular Health Education.

(For joint session see page 905.)

PUBLIC HEALTH NURSING

*Luncheon Session—Tuesday**First Session—Tuesday Afternoon*

Getting Public Health Needs Across to Appropriating Bodies.

By a Municipal Health Department. HENRY F. VAUGHAN, D.P.H., Commissioner of Health, Detroit, Mich.

By a Rural Nursing Organization. ELIZABETH A. RUSSELL, R.N., Director, Provincial Public Health Nurses, Winnipeg, Man.

By a Community Fund Agency. HELEN V. STEVENS, R.N., Director, Public Health Nursing Association, Pittsburgh, Pa.

Discussion.

Prenatal Nursing in the Province of Quebec. ALICE AHERN, R.N., Assistant Superintendent in Charge of Canadian Service, Metropolitan Life Insurance Company, Ottawa, Ont.

Public Health Nursing Education. LILLIAN HUDSON, R.N., Department of Nursing, Teachers College, Columbia University, New York, N. Y.

(For joint session see page 905.)

EPIDEMIOLOGY SECTION

First Session—Monday Morning

Evidences of Community Protection Against Diphtheria through Use of Toxoid. WILLIAM WARWICK, M.D., D.P.H., District Medical Officer of Health, St. John, N. B.

The Epidemiology of Scarlet Fever in Relation to Sinus Infection. A. CLEMENT SILVERMAN, M.D., Department of Health, Syracuse, N. Y.

A Milk-borne Typhoid Outbreak at Lincoln, Concord and Weston, Mass. M. J. ROSENAU, M.D., Harvard Medical School, Boston, Mass.

An Epidemiological Study of Amebiasis. From State Department of Health, Nashville, Tenn.

Typhoid Fever in Knoxville. WILLIAM H. ENNEIS, M.D., Bureau of Health, Knoxville, Tenn., and D. F. MILAM, State Department of Health, Nashville, Tenn.

Typhoid Fever in Richmond, Virginia. ALLEN W. FREEMAN, M.D., Professor of Public Health Administration, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

Current Estimation of the Population Susceptible to Measles. A. W. HEDRICH, Sc.D., School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

Epidemiological Practice through the Services of the Medical Practitioner. F. C. MIDDLETON, M.D., Deputy Minister, Department of Health, Regina, Sask.

(For joint sessions see pages 906 and 907.)

MEETINGS OF OTHER ORGANIZATIONS

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS

First Session—Monday—2 P.M.

Presiding, SVEN R. LOKRANTZ, M.D., President, American Association of School Physicians, Los Angeles, Calif.

Addresses of Welcome:

HIS WORSHIP CAMILLIEN HOUE, Mayor of Montreal.

WILLIAM C. HASSLER, M.D., President Elect, American Public Health Association, Health Officer, San Francisco, Calif.

Presidential Address. SVEN LOKRANTZ, M.D., Los Angeles, Calif.

The School Physician and the School Program. JOHN SUNDWALL, M.D., University of Michigan, Ann Arbor, Mich.

Medical Direction of All School Health Service. JOHN E. BURKE, M.D., Schenectady, N. Y.

No Title. ARNOLD H. KEGEL, M.D., Chicago, Ill.

Second Session—Tuesday—9.30 A.M.

Presiding, SVEN R. LOKRANTZ, M.D.

The Early Recognition of Cardiopathic Conditions in Children of School Age. ROBERT H. HALSEY, M.D., New York, N. Y.

The Incidence of Heart Disease Among Children of School Age. J. V. DEPORTE, M.D., Albany, N. Y.

Preventive and Remedial Measures in Heart Diseases of Children. LAURA B. BENNETT, M.D., Los Angeles, Calif.

Luncheon Session—Tuesday—12.30 P.M.

Presiding, SVEN R. LOKRANTZ, M.D.

Business Session—Tuesday Evening—8 P.M.

Presiding, SVEN R. LOKRANTZ, M.D.

Report of Officers.

Report of Committees.

Election of Officers.

Miscellaneous.

Third Session—Wednesday—9:30 A.M.

Presiding, S. BOUCHER, M.D., D.P.H., Director, Department of Health, Montreal, Que.

Natural and Acquired Posture. JAMES F. ROGERS, M.D., U. S. Bureau of Education, Washington, D. C.

The Recognition and Management of Tuberculosis of Childhood. HENRY D. CHADWICK, M.D., Detroit, Mich.

Tuberculosis Illustrated. STEPHEN A. DOUGLASS, M.D., Valley View Sanitarium, Paterson, N. J.

The Need for Promoting Interest in Convalescent Care. E. H. LEWINSKI CORWIN, M.D., Academy of Medicine, New York, N. Y.

Securing Results in Mouth Hygiene. HARRIS R. C. WILSON, D.D.S., Cleveland, O.

Fourth Session—Thursday—9.30 A.M.

Presiding, EDWARD PERCEY LEWIS, M.D., University of Toronto, Toronto, Ont.

Abnormal Behavior in the Adolescent from the Viewpoint of Endocrinology. WALTER TIMME, M.D., New York, N. Y.

The Hurried, Worried High and Junior High School Girl. A. L. BRANNACK, M.D., Pontiac, Mich.

The Psychological Factor in the Medical Examination of School Children. CATHERINE BRANNICK, M.D., Chicago, Ill.

The Relation of the Psychiatrist to the School Physician. FREDERICK L. PATRY, M.D., Albany, N. Y.

Fifth Session—Thursday—2 P.M.

Presiding, A. GRANT FLEMING, M.D., Professor of Public Health and Preventive Medicine, McGill University, Montreal, Que.

County and Rural Health Service.

In Canada. L. R. VEZINA, M.D., St. Jerome, Que.

In South Dakota. MARGARET W. KOENIG, M.D., Huron, S. Dak.

In Montgomery County, New York. ORRA A. PHELPS, M.D., Fort Plain, N. Y.

In Oakland County, Michigan. JOHN D. MONROE, M.D., Pontiac, Mich.

In Cattaraugus County, New York. CLARENCE A. GREENLEAF, M.D., Olean, N. Y.

The Integration of Health Agencies for the Health of the School Child. FRANCIS H. BARBOUR, Mineola, N. Y.

(For joint dinner see page 910.)

CONFERENCE OF STATE SANITARY ENGINEERS

All day Saturday and all day Monday. Annual Engineers' Stag Dinner Party, Wednesday evening.

ASSOCIATION OF WOMEN IN PUBLIC HEALTH

Dinner. Monday evening.

CONFERENCE OF STATE LABORATORY DIRECTORS

(Limited to Directors of State and Provincial Laboratories, Branch Laboratories and their Chief Assistants.)

Luncheon Session. Tuesday.

Afternoon Session. Tuesday.

INTERNATIONAL ASSOCIATION OF DAIRY AND MILK
INSPECTORS

Thursday, Friday, and Saturday, September 10, 11, and 12.

AMERICAN SOCIAL HYGIENE ASSOCIATION AND THE
CANADIAN SOCIAL HYGIENE COUNCIL

Wednesday. One day Social Hygiene Institute.

INTERNATIONAL SOCIETY OF MEDICAL HEALTH OFFICERS
Week of September 14.

DELTA OMEGA

Luncheon. Monday.

SYMPOSIUM ON BRITISH PUBLIC HEALTH
ADMINISTRATION

ON Tuesday afternoon a special session on Health Administration in Great Britain will be held. The speakers will be:

Sir Allan Powell, Chief Public Assistance Officer, London County Council, London

George F. Buchan, M.D., M.R.C.P., D.P.H., Medical Officer of Health, Willesden, London

James Fenton, M.D., D.P.H., Medical Officer of Health, Kensington, London

Charles Porter, M.D., B.Sc., Medical Officer of Health, Marylebone, London

They will discuss trends in British public health administration, education and training of public health workers, maternal and infant health services and hospital administration.

*Upper—Christ Church Cathedral (Anglican), a fine example of early English architecture

INSPECTION TRIPS FOR THE A. P. H. A. CONVENTION MONTREAL, CANADA, SEPTEMBER 14-17, 1931

THEODORE J. LAFRENIERE, F. A. P. H. A.

*Chief Engineer, Provincial Department of Health; and Chairman, Committee on
Inspection Trips of the Local Committee, Montreal, Canada*

MONTREAL, the metropolis of Canada, offers a wealth of sanitary works, construction projects, hospitals and kindred institutions and industrial plants for inspection trips. The committee in charge has made arrangements for a number of visits which will satisfy every variety of interest in public health work.

It must be remembered that the city

of Montreal is one of the principal historic centers on the continent—it abounds in sites each of which brings to the memory a stirring story of heroism or gallantry. Champ de Mars, Place d'Armes, Jacques Cartier Square—these are places that thousands of tourists come to visit every year. In consequence, the inspection trips will provide a rare opportunity to see in detail historic Montreal, as well as to examine features of particular importance to public health workers.

It may be recalled too that Montreal constitutes a link between the Old World and the New. French is spoken by the great majority of its citizens, and many features brought back from France have been incorporated into the practice of many of the hospitals, health centers and similar institutions. English practice too finds many proponents in this new-old-world city. As a result, a notable combination of French, English, and American methods will be found in the work of practically all the larger medical and public health institutions, a feature which will prove of exceptional interest to workers in similar fields.

One of the main features to be included in the inspection trips is the Municipal Water Filtration Plant with a total capacity of 250 million gallons per day. The plant employs double filtration for part of the supply, a practice unique in water treatment on this side of the Atlantic. The major portion of the city's water is handled by mechanical gravity filters. These two types of filtration, with their various equipment.

Bonsecours, the sailors' church, built in 1771 on site of first church erected in 1657. Dozens of tiny ships holding votive lamps, given in recognition of answered prayers for safety, decorate the interior.

should prove of exceptional interest. Other features of interest to the sanitary engineer will include the construction work in progress on two main sewage collectors of the tunnel type. The novel method of construction used in this work will be well worth inspection. A new incinerator, of the most modern design and just placed in operation, will be visited. And for those interested in milk sanitation engineering, Montreal possesses several modern pasteurization plants, one of which, recently built, is the last word in pasteurization design and equipment.

A variety of municipal health centers, as well as county health units in operation a short distance from the city, may be visited. Here the combination of French and English, as well as American features, with bi-lingual officers and attendants, will be novel to the experience of many in this line of work. It is perhaps not generally appreciated that the Province of Quebec has made amazing progress during the past 5 years in its rapid installation of county health units. No less than 23 such units, to cover 29 counties, have been organized in this short period. A visit to one of these units will show the manner in which the Province hopes to solve its rural health problem.

The laboratory worker will doubtless be interested in the Provincial and Municipal Health Laboratories. The former employs a staff of 35 and is provided with an excellent equipment. It made over 100,000 examinations last year.

Montreal possesses a great variety of hospitals and related institutions—some religious, some nondenominational. Of the French hospitals, the Notre-Dame, the Hotel-Dieu, the Ste. Justine Hospital for Children, will prove of particular interest. The large Montreal General Hospital as well as the Royal Victoria and Montreal Children's Hospitals, ideally located on the slopes of Mount Royal, are well worth a visit.

Then there are the Radium Institute, the Sacred Heart Hospital for Tuberculosis and a number of smaller institutions. In addition there are four new hospitals under construction. Some of the larger charitable institutions and asylums, veritable cities in themselves

The statue of Paul Chomedey de Maisonneuve, founder of Montreal, stands on Place d'Armes near the spot where he slew the chief of an invading band of Iroquois.

and truly remarkable in breadth of organization and scope of activities, are of a type rarely encountered in cities on this continent. A beautiful side trip by motor will be arranged, if desired, to the Ste. Agathe Sanatorium for Tuberculosis, situated in the Laurentian Mountains.

Among the industrial plants to be visited which may be of interest are the large sugar refineries and the Fleishmann Yeast Plant. And we may not forget the Frontenac Brewery, a type of plant rather foreign to the experience of many of our neighbors on the other side of the boundary line, but which will prove well worth a visit.

ASSOCIATION NEWS

NOMINATIONS FOR THE GOVERNING COUNCIL

IN accordance with the By-laws of the Association the Nominating Committee reports the following nominations for the Governing Council. The Constitution provides that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, providing

such petition is received 15 days before the Annual Meeting."

The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in Montreal will be elected for the three-year term, 1931-1934.

William J. Bell, M.B.,
Deputy Minister of Health,
Toronto, Ont.

Richard A. Bolt, M.D.,
Director, Cleveland Child Health Assn.,
Cleveland, O.

Homer N. Calver,
Asst. Professor of Hygiene,
Univ. & Bellevue Hospital Medical College,
New York University,
New York, N. Y.

Michael M. Davis, Ph.D.,
Julius Rosenwald Fund,
Chicago, Ill.

W. J. V. Deacon, M.D.,
Director, Bureau of Records & Statistics,
State Board of Health,
Lansing, Mich.

Robert D. Defries, M.D.,
Connaught Labs., Univ. of Toronto,
Toronto, Ont.

Harrison P. Eddy,
Consulting Engineer,
Boston, Mass.

W. Brownley Foster, M.D.,
Director of Public Welfare,
Richmond, Va.

Walter S. Frisbie,
U. S. Food, Drug & Insect Control,
Department of Agriculture,
Washington, D. C.

Omer R. Gillette, M.D.,
Health Officer,
Colorado Springs, Colo.

Edward S. Godfrey, Jr., M.D.,
Dir., Division of Communicable Diseases,
State Department of Health,
Albany, N. Y.

Annie W. Goodrich, R.N.,
School of Nursing, Yale University,
New Haven, Conn.

Prof. F. P. Gorham,
Brown University,
Providence, R. I.

Clarence F. Kendall, M.D.,
State Commissioner of Health,
Augusta, Me.

John W. Kerr, M.D.,
U. S. Public Health Service,
Washington, D. C.

W. F. King, M.D.,
State Health Commissioner,
Indianapolis, Ind.

John P. Koehler, M.D.,
Commissioner of Health,
Milwaukee, Wis.

George T. Palmer, D.P.H.,
Director, Division of Research,
American Child Health Association,
New York, N. Y.

George M. Parrish, M.D.,
Health Officer,
Los Angeles, Calif.

Raymond S. Patterson, Ph.D.,
Life Conservation Service,
John Hancock Mutual Insurance Co.,
Boston, Mass.

W. H. Peters, M.D.,
Health Officer,
Cincinnati, O.

John T. Phair, M.B.,
Department of Health,
Toronto, Ont.

Mazÿck P. Ravenel, M.D.,
University of Missouri,
Columbia, Mo.

John L. Rice, M.D.,
Health Officer,
New Haven, Conn.

James Roberts, M.D.,
Medical Officer of Health,
Hamilton, Ont.

William F. Snow, M.D.,
General Director, American Social Hygiene
Assn.,
New York, N. Y.

Henry Field Smyth, M.D.,
Laboratory of Hygiene,
University of Pennsylvania,
Philadelphia, Pa.

Stewart G. Thompson, D.P.H.,
Director, Bureau of Vital Statistics,
State Board of Health,
Jacksonville, Fla.

Robert Spurr Weston,
Consulting Engineer,
Boston, Mass.

Anna W. Williams, M.D.,
Research Laboratory,
Department of Health,
New York, N. Y.

CHARLES V. CRASTER, M.D.,
Chairman,
Nominating Committee.

APPLICANTS FOR FELLOWSHIP

HEALTH OFFICERS' SECTION: Seraphin Boucher, D.P.H., Montreal, Que.; Earle G. Brown, M.D., Topeka, Kansas; Willis N. Butrick, Milford, Conn.; Jay Dee Dunshee, M.D., Pasadena, Calif.; Jesse H. Epperson, Durham, N. C.; Cameron St. Clair Guild, M.D., New York, N. Y.; David E. Smallhorst, M.D., Glendale, Calif.; James Stewart, M.D., Jefferson City, Mo.; William B. Wells, M.D., Riverside, Calif.; William F. Wild, M.D., Bridgeport, Conn.

LABORATORY SECTION: Oscar Costa-Mandry, M.D., San Juan, P.R.; W. T. Cummins, M.D., San Francisco, Calif.; Frederick W. Fabian, Ph.D., East Lansing, Mich.; Donald T. Fraser, M.B., Toronto, Ont.; William D. Frost, Dr.P.H., Madison, Wis.; C. A. Perry, Hurlock, Md.; R. V. Stone, M.D., Los Angeles, Calif.; Arthur N. Tasker, M.D., Fort Lewis, Wash.; Joseph C. Willett, D.V.M., St. Louis, Mo.; Verna Willis, M.S., Jefferson City, Mo.

PUBLIC HEALTH ENGINEERING SECTION: Harold A. Young, Los Angeles, Calif.; Ernest William Steel, C.E., College Station, Tex.

CHILD HYGIENE SECTION: Amos L. Beaghtler,

M.D., Denver, Colo.; Mary Luise Diez, M.D., Boston, Mass.; P. Martin Keller, M.D., Glendale, Calif.; Anastasia Miller, R.N., Sacramento, Calif.; Harry K. Read, M.D., Houston, Tex.

PUBLIC HEALTH EDUCATION SECTION: Edna W. Bailey, Ph.D., Berkeley, Calif.; Mary P. Connolly, Detroit, Mich.; Charles F. Hayes, M.D., Fort Worth, Tex.; Arthur Jordon, M.D., Helena, Mont.; Anne Raymond, New York, N. Y.; James R. Scott, M.D., Albuquerque, N. M.

PUBLIC HEALTH NURSING SECTION: Mrs. Ivah W. Uffelman, Nashville, Tenn.

EPIDEMIOLOGY SECTION: Albert E. Austin, M.D., Sound Beach, Conn.; Jesse H. Crouch, M.D., Helena, Mont.; James A. Doull, M.D., Cleveland, O.; H. W. Hill, M.D., Vancouver, B. C.; A. Clement Silverman, M.D., Syracuse, N. Y.; George M. Stevens, M.D., Los Angeles, Calif.; Ida M. Stevens, Berkeley, Calif.

UNAFFILIATED: John H. Collins, M.D., Schenectady, N. Y.; Frank L. Watkins, M.D., Great Falls, Mont.; Paul L. West, M.D., Wenatchee, Wash.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A. P. H. A. by the Sub-committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

Margaret W. Barnard, M.D., New York, N. Y.,
Medical Director, Bellevue-Yorkville Health
Demonstration
O. I. Bemis, M.D., Modesto, Calif., Stanislaus
County Health Officer

Dr. Thomas M. Berry, Okmulgee, Okla., Supt.
of Public Health
Edward R. Davies, M.D., Georgetown, Ky.,
Director, Scott County Health Dept.
L. G. Eastman, M.D., Hazen, N. D., Supt. of
Public Health, Mercer County

Francis E. Gibson, Monessen, Pa., City Health Officer

Aurel Goodwin, M.D., Topeka, Kans., City Health Officer

George N. MacDonnell, M.D., Miami, Fla., Chief, Division of Health

T. J. McNally, M.D., London, Ont., District Officer of Health

H. M. Mosdell, M.D., St. John's, Newfoundland, Chairman, Board of Health

Hon. George H. Murphy, M.D., Halifax, N. S., Minister of Public Health

Fred L. Ogilvie, Caruthersville, Mo., Pemiscot County Health Officer

James E. Pendergrass, M.D., Fresno, Calif., Fresno County Health Officer

Laboratory Section

Koji Ando, M.D., New York, N. Y. (Chief, Bacteriological Dept., Hygienic Inst. of S. M. R. Co., Dairen, S. Manchuria, China) (Assoc.)

M. Jacques Archambault, B.A., C.E., Montreal, P. Que., Chemist, Provincial Bureau of Health

M. Jules Archambault, M.D., Montreal, P. Que., Serologist, Provincial Bureau of Health

Antonio Bolduc, M.D., Montreal, P. Que., Bacteriologist, and Supt., Division of Labs, Dept. of Health

Joseph Felsen, M.D., New York, N. Y., Director of Labs and Research, Bronx Hospital

Michael Horti, M.D., Woodhaven, L. I., N. Y. (Assoc.)

Luang Siribaed-bisuddhi, C.P.H., Dr.P.H., Washington, D. C. (temporarily), Director of Public Health Labs., Bangkok, Siam (Assoc.)

Public Health Engineering Section

Samuel D. Macready, Hollywood, Fla., Director of Health and Sanitation

Harvey G. Rogers, Minneapolis, Minn., Sanitary Engineer, State Dept. of Health

Industrial Hygiene Section

Sophie Rabinoff, M.D., New York, N. Y., Bureau of Industrial and Adult Hygiene, Dept. of Health

Child Hygiene Section

Eleanor B. McCarthy, B.S., Boston, Mass., Consultant in Dental Hygiene, State Dept. of Health

J. F. Mosher, M.D., Coeymans, N. Y., School Physician

Public Health Education Section

Louise F. Bell, Pasadena, Calif., Chairman, Committee on Health and Sanitation, Women's Civic League

Frances Daniel, Chicago, Ill., Educational Worker, National Food Bureau (Assoc.)

Edith M. Gates, B.A., New York, N. Y., Director, Health Education, National Board, Y. W. C. A.

Dwight G. W. Hollister, B.B.A., Babson Park, Mass. (Assoc.)

Dr. William D. Moore, San Pedro, Calif., City School Physician (Los Angeles)

Robert L. Nourse, M.D., Boise, Idaho, Public Health Adviser, Dept. of Public Welfare

R. R. Rosell, Chicago, Ill., Educational Worker, National Food Bureau (Assoc.)

Mildred L. Tuttle, R.N., Nashville, Tenn., Instructor, Health Education and Nursing, Peabody College

Public Health Nursing Section

Lalla M. Goggans, R.N., Jacksonville, Fla., Staff Nurse, State Board of Health

Mary Harrigan, R.N., Detroit, Mich., Territorial Supv., Metropolitan Life Ins. Co.

Mrs. Condon W. Taylor, R.N., Nashville, Tenn., Field Nurse, State Dept. of Public Health

Unaffiliated

John M. Flude, M.D., New York, N. Y., Field Representative, American Society for Control of Cancer

DECEASED MEMBERS

George M. Kober, M.D., Washington, D. C., Elected Member 1896, Fellow 1922

Mrs. Herman M. Biggs, New York, N. Y., Elected Member 1926 (Assoc.)

Horace G. Dunham, M.D., Dover, N. J., Elected Member 1926

Edgar B. Kay, Washington, D. C., Elected Member 1928

Anne McFarland Sharpe, M.D., Tallahassee, Fla., Elected Member 1927

Col. Gustave R. Tuska, New York, N. Y., Elected Member 1915

William E. Warren, M.D., Williamston, N. C., Elected Member 1920

Ennion G. Williams, M.D., Richmond, Va., Elected Member 1905

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Health Survey of Washington—
A study of health and hospital service has been made in Washington, D. C., by the staff of the American Public Health Association with the aid of other agencies. On the basis of the *Appraisal Form*, this city scores 725.6. The effort of the Health Department contributes 73.7 per cent of this total, while 14.8 per cent is due to other official agencies, and 11.5 per cent is due to the efforts of voluntary agencies.

The health department rates 87 per cent in its vital statistical service. There are deficiencies in the analysis and graphic presentation of facts and it is recommended that a trained statistician be employed with suitable personnel and that there be installed mechanical devices for the analysis of data.

All of the acute communicable diseases are well reported with the exception of typhoid fever. The number of children protected against diphtheria is comparatively small but vaccination of school children against smallpox is compulsory. There is need for a continuous and vigorous diphtheria protection campaign. There is also need for additional trained public health nurses to replace medical inspectors who should be used only for diagnostic service.

There is need of effort to increase the reporting of venereal infection and the tracing of sources of infection among clinic cases. There should be a full-time director of the tuberculosis service with an extension of medical, nursing, hospital, and preventive services.

Washington scores 86 per cent in maternal hygiene work but only 66 per cent in infant hygiene, where material increases are needed in medical and nursing personnel.

School health service is a joint function of the Health Department and the Board of Education. The number of medical inspectors, school nurses, and dental inspectors should be increased in order to provide a thorough medical examination of all children entering public school for the first time, and of children in the fifth or sixth grades, and to enable the nurses to encourage the mothers to bring a large number of children with defects to professional attention.

The rating for food and milk control is 87 per cent, while the sanitation activities have the highest rating of any division of the department with a score of 92 per cent.

Funds and personnel should be provided to make possible a popular health instruction bureau in the health department.—*Health and Hospital Survey of Washington, D. C.*, Washington Council of Social Agencies, 1931.

Rural Health in Missouri—Contagion and nutritional deficiencies have increased in the drought areas of Missouri. This is especially true of typhoid fever. Scurvy, pellagra, and rickets have been reported to be more prevalent. Nutritional disturbances may lead to an increase in the prevalence of tuberculosis.

With the coöperation of the U. S. Public Health Service, funds became available in February, 1931, for the establishment of a division of coöperative rural health work in the State Health Department. The plan contemplates the establishment of five rural health districts south of the Missouri River, each under the supervision of a full-time trained district health officer,

assisted by a public health engineer, nurses, and laboratory technicians.—James Stewart, State Health Commissioner, Missouri's Efforts to Protect Health of Rural Inhabitants, *United States Daily*, May 29, 1931.

Examination of Domestic Servants in Newark, N. J.—The Health Department, having successfully required a semiannual examination of food handlers for several years, concluded that it would be possible, and undoubtedly valuable, to extend this work to include a similar requirement for domestic servants where intimate contact with the family is certain. Accordingly, an ordinance was adopted September 1, 1930, requiring a certificate of health from a physician for each domestic servant, indicating that the individual has been found free from tuberculosis or any other communicable disease. The certificate is submitted on blanks supplied by the Newark Health Department and is good for a period of 6 months. Upon receipt of the certificate, the Health Officer issues a food handlers' card. The ordinance further states that any domestic servant desiring to conform to the provisions of the ordinance may be examined by a physician connected with the Newark Health Department without charge.

The law is administered in much the same manner as the food handlers' ordinance with the exception that enforcement is a function of the sanitary rather than the food division of the Health Department. The physical examinations are made by physicians in the tuberculosis division.

During the 8-month period following the adoption of the ordinance, there have been examined 2,196 domestics, of whom 2,107 were females. Of this number, 1,382 were colored and 814

white. There were 1,769 housekeepers and houseworkers, 151 cooks, 25 nurse maids, and 251 in a miscellaneous group. This is considered a fairly satisfactory start as it is realized that the numbers will increase steadily as the public, through constant publicity, becomes familiar with the ordinance. It is understood, of course, that the 25 nurse maids represented but a fraction of the thousands of individuals employed in this type of service. It is the intention of the Health Department to seek wilful offenders and bring them to court with the belief that the subsequent publicity will increase the number of applicants for examination.—Charles V. Craster, Health Officer, Newark, N. J., July, 1931.

Variable Scarlet Fever Quarantine—Following a 5-year study of the incidence of secondary cases in scarlet fever, the Detroit Department of Health has adopted a variable quarantine period for scarlet fever based not only upon the clinical condition of the patient but also upon age and weather. In the past, a simple case of scarlet fever was quarantined for 28 days while the complicated case was held for a maximum of 56 days. The new regulations provide for a 21-day quarantine for patients 15 years of age and over, while children below this age are still held for 28 days. Also, during the warm months of July, August, and September, the quarantine period at all ages is reduced to 21 days, as the infecting case rate during this period has for the past several years been less than 1 per cent. In complicated cases at the end of 28 days the quarantine is removed and a warning placard restricts the case until termination of the period of isolation.—*Weekly Health Review*, Detroit Dept. of Health, June 27, 1931.

LABORATORY

JOHN F. NORTON, PH. D.

A TWO-PHASE AND THREE-PHASE AUTOMATIC INOCULATOR FOR BACTERIOPHAGE WORK

FRED O. TONNEY, M. D., F. A. P. H. A.

Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

THE two types of apparatus described were improvised to avoid the necessity of manual inoculations at night, in obtaining successive generations of young cultures for bacteriophage studies. The smaller device with the single alarm clock provides a second generation culture ready for morning use, and the larger one with the double clock attachment gives a third generation culture.

The age of the culture is fixed by setting the alarm hands of the clocks at any time desired. The time gained by having young cultures ready in the morning is often of material aid in the day's work.

The parts required to be sterilized are easily detached at the hose connections. They are made up and prepared a number at a time, cotton plugged at all open ends, wrapped in paper, sterilized and kept ready for use.

PARTS

1. The alarm clock, Figure 1, is of the ordinary type, but should have an alarm spring of ample strength. It is fitted with an extension wing of heavy tin $1\frac{1}{4}$ " wide, attached by screws to the alarm winding stem (a) and a horizontal shelf of tin $1\frac{1}{4}$ " wide screwed to the body of the clock (b). Before this shelf is attached the alarm stem should be wound to its full tension. When in use, the alarm hand is set in the usual way and when the alarm rings the winding stem moves downward until stopped by the horizontal shelf, thus acting as a lever to compress a rubber bulb placed upon the shelf. In purchasing the clock, one having a short

margin time for setting the alarm should be selected.*

2. The inoculating pipette, Figure 2, consists of a combination T tube and U tube of ordinary 6 mm. glass tubing with a rubber bulb (3 to 5 c.c.) on one end and an air vent of rubber tubing compressed by a screw clamp on the projecting arm. The pipette is most simply made from an ordinary T tube by bending one arm to form a shallow U and drawing out the distal end to a tip which is then bent downward at an angle. A small safety bulb may be blown in the tube next to the U if desired.

3. The T tube, Figure 3, of 6 mm. tubing fitted at one end with a larger bulb (5 or 10 c.c.) and an air vent of rubber tubing and screw clamp on the projecting arm.

* To illustrate: If the alarm hand is set at 4 A.M. the alarm lever can usually be moved from the "silent" to the "ringing" position after 4:30 P.M. the previous evening, without tripping the alarm. Some clocks, however, require a margin of as much as two hours in the setting time. The most serviceable clock is one having a time margin of $\frac{1}{2}$ hour or less. A watch-maker can usually readjust the mechanism to give a shorter time margin.

FIGURE 2

4. A standard U tube, Figure 4, of any size desired (a) with side arms. To one arm is connected, by means of rubber tubing, a small delivery tube with a narrowed tip, bent at a right angle (b).

5. Several solid rubber stoppers to fit the standard U tube, Figure 4 (a).

6. A small ring stand, small clamp and clamp holder.

THE SINGLE INOCULATOR

The single device consists of a clock and an inoculating pipette, Figures 1 and 2. The complete assembly is shown in Figure 6.

The steps of the technic of preparation are as follows:

1. Wind the clock and set the alarm hand at the inoculating time desired. Turn alarm lever to "silent."

2. Place clock and all unassembled parts in the incubator for 1 hour to warm; include a small flask of sterile broth to be inoculated at the outset.

3. After warming, unwrap the sterile in-

oculating pipette, attach the bulb and vent, leaving the cotton plugs in the tubes. Open the vent; see Figure 6.

4. Inoculate the warmed flask of broth with a culture of the organism to be used. The mouth of the flask should be wide enough to admit the inoculating pipette (about 1").

5. Dip the inoculating pipette into the flask just inoculated and draw up enough fluid to fill the U, controlling the manipulation by pinching or releasing the opened vent with the fingers. Remove the pipette from the flask to a horizontal position and adjust the fluid in the U tube to the amount desired by again manipulating the bulb and opened vent. In the same way blow out the last drop from the tip.

6. Now flame the tip thoroughly until it is completely dry and sterile inside and out (keep vent open).

7. Insert the sterile tip beside the cotton plug of a second flask of sterile broth (keep vent open).

8. Assemble the outfit in the incubator, placing the bulb between the compression arms of the clock (vent open).

9. Allow the outfit to warm one-half hour;

then set the alarm lever to ring, close vent and leave the apparatus in the incubator over night.

The first phase of growth occurs in the inoculating pipette. When the alarm rings the flask of broth is inoculated from the contents of the pipette and the second phase of growth begins.

THE DOUBLE INOCULATOR

The double device consists of two alarm clocks, Figure 1; one inoculating pipette with bulb and vent, Figure 2;

THE "T" TUBE

FIGURE 3

one plain T tube with bulb and vent, Figure 3; one standard U tube, Figure 4 (a); with delivery tube, (b). The standard U tube is previously filled with broth to about $\frac{1}{2}$ " below the side arms; it is then cotton plugged and sterilized with the delivery tube, Figure 4 (b), in place but protected by a paper wrapping. Just before use, the cotton plug farthest from the delivery tube is replaced by a tightly fitting sterile rubber stopper. Assemble the apparatus as shown in Figure 5.

TECHNIC OF PREPARATION

1. Wind the clocks, set the alarm hands at the desired hours, as 10 P.M. and 4 A.M. Turn the alarm levers to "silent."

2. Place both clocks and all the unassembled parts in the incubator for about an hour to warm. Include also a small flask of sterile broth to be inoculated at the outset (g).

3. After warming, fasten the standard U tube (a) of sterile broth rigidly to a small ring stand by means of an adjustable clamp and clamp holder. Turn the cotton plugged arm forward (the one next to the delivery tube) and replace the rear cotton plug with the sterile rubber stopper.* See that the U tube is filled to within $\frac{1}{2}$ " below the side arms. Tip the forward arm downward until the level of fluid is just below the outlet to the delivery tube.

4. Assemble the apparatus around the U tube (a) and stand as in Figure 7 (all vents open).

Thus:

1. The sterile delivery tube (b) of the U tube is unwrapped, flamed and inserted beside the cotton plug of a second flask of sterile broth (c) for the final inoculation of the series. Caution: The tip must be kept dry. A drop of fluid in it will block the siphon, which operates when the clock rings.

2. To the side arm of the U tube opposite the delivery tube is connected the T tube (d) with vent and bulb (e), the cotton plug in the side arm being left in place.

3. The bulb (e) is placed between the compressor arms of clock No. 2, at the right of the stand.

4. The previously warmed flask of sterile broth (g) is now inoculated with the organism to be used, and shaken.

5. From the flask just inoculated, a sterile inoculating pipette (f) is filled by dipping the tip into the flask (g), drawing the fluid into the U, withdrawing the pipette and adjusting the amount retained by manipulating the bulb and opened vent.

STANDARD "U" TUBE

FIGURE 4

* The rubber stopper must be tight. It forms the seal of the compressor device, which holds the positive pressure to start the siphon, and the negative pressure to stop it.

FIGURE 5

6. Flame the tip of the inoculating pipette thoroughly until dry and sterile and insert it beside the cotton plug of forward arm of the U tube (a) (vent open)

7. Place the bulb end of the inoculating pipette (f) between the compressor arms of clock No 1, which is placed to the left and to the rear of the stand, beside clock No. 2 for economy of space (vent open).

8. Place completely assembled outfit in the incubator (all vents open) and allow to warm for one-half hour.

9. Set alarm levers to ring, close vents tightly, tighten rubber stopper at (a) securely, and leave apparatus in the incubator over night.

10. Go to bed and sleep with confidence. The third generation culture will be ready for you in the morning.

The first phase of growth occurs in the inoculating pipette (f) as in the single inoculator. The second phase begins in the standard U tube (a) when clock No. 1 rings. The third takes place in the flask (c) beginning when

clock No. 2 rings, usually at 3 or 4 A.M., and gives rise to the desired third generation culture for morning use.

Arrangements have been made with the Central Scientific Company, Chicago, to furnish the essential parts and complete assembly ready for use.

KEEPING QUALITY OF KAHN ANTIGEN AFTER CHOLESTEROLIZATION

FANNIE MAE FRANK

Laboratories of Alabama State Board of Health, Montgomery, Ala.

KAHN¹ recommends that antigen, after the cholesterol has been added, be not used after 2 months. It has been our practice to adhere strictly to this procedure and discard any cholesterolized antigen more than 2 months old. Since the antigen is prepared in the Central Laboratory for use in 8 branch laboratories, this practice involves considerable waste, even though the needs of each laboratory are anticipated as carefully as possible.

In Table I are given the results of parallel tests with freshly cholesterolized antigen and several lots to which cholesterol had been added from 1 to 2 years before the tests. It seems ap-

TABLE I

Antigen	Age	No. of Tests	No. of Disagreement
3 F	2 years	106	1 (2 + with 3 F; negative with 10 C)
4 A	2 years	116	2 (negative with 4 A; neg. Kolmer test)
7 A	18 months	90	0
9 B	12 months	98	0
Total		410	3

parent that the cholesterolized antigen is entirely satisfactory for periods of at least 1 year.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Traffic Accidents in Tokyo, 1930
—With the remarkable increase in the number of motor cars in Tokyo, street accidents occurred so frequently that in 1930 deaths and injuries averaged 47 every day. According to the statistics of the Metropolitan Police in Tokyo, during last year there were 28,953 accidents, 17,062 of which resulted in the death or injury of the victims.

There were 17,124 motor car accidents, with 8,890 persons killed or injured; 6,205 bicycle accidents, with 4,504 persons injured or killed; tramway cars were the means of 2,929 accidents and 1,386 persons injured or killed. Accidents of motorcycles have been increasing year by year, the number of deaths during 1930 being more by 150 than the number for 1929. The total number of motorcycle accidents in 1930 was 1,298, with 892 injuries and deaths.

Pedestrians were the means of 558 accidents with 538 resulting injuries and deaths. According to the new regulation published last year, the injured pedestrians are to be punished in case they induce the accidents through their own carelessness.—*J. A. M. A.*, 96: 1968 (June 6), 1931.

Vital Statistics for Michigan, 1930
—Final figures for 1930 show Michigan to have achieved two record rates, the lowest death rate and the lowest infant mortality rate in the history of the state. Moreover, the maternal mortality rate was one of the three lowest in Michigan's history.

There were 51,561 deaths in Michigan during 1930, equivalent to a death rate of 10.6 per 1,000 population. This compares with the preceding 4 years:

1929 and 1928 with a rate of 11.9, 1927 with a rate of 11.3, and 1926 with a rate of 12.4.

In spite of the increase in the state's population, there were 4,556 less deaths than in 1929. There were 6,217 deaths of children under 1 year of age in Michigan in 1930, which is equivalent to an infant mortality rate of 62.9 per 1,000 live births. The rate in 1929 was 66.9. A generation ago, in 1900, this rate was 157.1. This makes the rate for 1930 only about 40 per cent of what it was 30 years ago.

There were 584 deaths in Michigan in 1930 from puerperal causes, which gives a maternal mortality rate of 5.9 per 1,000 living births, compared with 6.3 in 1929. This was bettered only by the rate of 5.7 in 1912, and 5.8 in 1916. The maternal mortality rate in 1900 was 10.3, a reduction of almost one-half in 30 years.

Michigan's birth rate for 1930 fell from 20.9 per 1,000 of population in 1929 to 20.4 in 1930. There were 98,882 births, 187 more than in 1929, but not a sufficient gain to hold the rate in the face of the increase in population. Comparison of the birth rates for the past 5 years shows a steady decrease in birth rates, from 22.5 in 1926; 22.3 in 1927; 21.2 in 1928; 20.9 in 1929; to the 1930 birth rate of 20.4. This falling birth rate is by no means peculiar to Michigan. Advance reports from various states indicate that a number of them will show a rate under 20 for 1930.—*Michigan Public Health*, 19: 75 (Apr.), 1931.

The Health of Ceylon, 1929—
With an estimated population of 4,750,000, the birth rate of Ceylon in

1929 was 36.8 per 1,000 population; the death rate 24.9; and the infant mortality rate 183 per 1,000 births. While Ceylon is particularly unaffected by outbreaks of insect-borne disease, it is greatly troubled by malaria. In Colombo alone, in 1929, 3,268 cases of malaria were admitted to the general hospital, 154 of these proving fatal. Cholera was responsible for 28 cases and 23 deaths, giving a fatality rate of 82.1. Eighty cases of plague occurred, of which 40 were in Colombo. Probably the greatest scourge of all, however, is hookworm disease. No less than 178,000 cases were treated in dispensaries, and 12,129 in hospitals; while the total number of deaths registered from hookworm disease was 2,172 for the island.

The total number of deaths in the last 5 years has not diminished, though it would appear that in certain districts the ankylostomiasis campaign is beginning to show results, as it is reported that the wards in hospitals in these districts are now almost empty. When it is considered that the bulk of the Asiatic population goes about barefooted, and that latrines, except in Colombo and some of the towns, are, if existent, but sparsely used, it is not surprising that it is difficult to reduce the incidence of this disease. Dental caries was found to be the most common ailment of the school children in Ceylon; and following this ailment, the next in importance was hookworm disease.—*Pub. Health*, 44: 243 (May), 1931.

Vital Statistics for Spain, 1930—According to provisional figures from the office of chief of statistics in Spain, there were 660,735 live births, and 394,355 deaths from all causes in 1930, resulting in a natural increase of 266,380 persons. Figures derived from 50 Spanish provinces, showed the birth rate for 1930 to be 29.03 per 1,000 population as against 28.92 in 1929,

with a stillbirth rate of 31.9 per 1,000 births, as compared with 31.4 in 1929. The rate for deaths from all causes was 17.33 per 1,000 population as against 18.03 in 1929. The infant mortality rate of 117 deaths of infants under 1 year of age per 1,000 live births shows an improvement over the 1929 figure of 123.

Among the diseases which showed a marked decline in mortality in 1930, the reduction in the death rate from all forms of tuberculosis was most striking—from 136.3 per 100,000 population in 1929 to 126.9 in 1930; pulmonary tuberculosis declined from 111.3 in 1929 to 103.3 in 1930. Pneumonia declined from 43.0 (1929) to 40.1 (1930); other diseases of the respiratory system, from 160.0 to 144.5; meningitis from 49.0 to 44.7; and organic diseases of the heart from 168.9 to 160.9. As contrasted with these reductions in death rates, the rate from cancer in Spain increased from 70.0 in 1929 to 72.3 in 1930; cerebral hemorrhage and softening of the brain showed an increase from 124.8 in 1929 to 125.7 in 1930; appendicitis and typhlitis, and cirrhosis of the liver showed slight increases, with rates in 1930 of 3.3 and 16.2 respectively.

Though there was a slight reduction in the death rate from typhoid fever, this disease caused 16.4 deaths per 100,000 population, in 1930. The death rate for diarrhea and enteritis under 2 years of age was 34.9 per 100,000 in 1930 as compared with 35.6 in 1929. Preliminary figures for deaths from suicide showed a death rate of 3.7 and violent deaths, excepting suicide, a rate of 29.—*Revista de Hygiene e Saude Publica*, 5: 195 (May), 1931.

Smallpox in the United States and Canada, 1930—Analysis of the reports received from 44 states, the District of Columbia and 6 Canadian provinces shows that there was a marked increase

in the incidence of smallpox in the United States, in 1930, but a decided decrease in the prevalence of this disease in Canada. There was recorded, in each country, a rise in the case fatality rate. Fortunately, however, the areas in which increases occurred were those in which there was a relatively low incidence of the disease.

Among the cities of the United States many had enormous smallpox sickness rates in 1930. In Waterloo, Ia., and Cleburne, Tex., there were 1,145 and 1,109 cases, respectively, per 100,000 population. Other very high rates prevailed in Davenport, Ia. (1,060); Ottumwa, Ia. (677); Sioux Falls, S. D. (594); Aberdeen, Wash. (566); Spokane, Wash. (543); Muncie, Ind. (490); Phoenix, Ariz. (453); New Philadelphia, O. (453). Rates between 300 and 400 were recorded for Quincy, Ill.; Des Moines, Ia., and Lima, O.

The rise in the prevalence of smallpox in the United States from 38,281 cases, in 1929, to 44,544 cases, in 1930, indicates a serious situation. But, disturbing as these figures are, their full significance is revealed only when it is realized that over 43,000 (97 per cent) of the 1930 cases occurred in states whose population aggregated but 54 per cent of the total population of the country. These states, in large part, are those in which anti-vaccination propaganda has been most active. In 2 states, Indiana and Ohio, there were reported over 5,000 cases each. California, Illinois and Iowa each reported over 3,000, and Kansas, Michigan, Oklahoma and Washington each had over 2,000 cases.

These figures may be compared with those reported by New England and the Middle Atlantic States, areas in which public support of the constituted health authorities for vaccination has been most responsive. Here, the country's most thickly populated region, a condition conducive to active propa-

gation of the disease, it is found that, among a population of approximately 37,000,000, there occurred only 479 cases and 2 deaths from smallpox, in 1930. To appreciate the full significance of these figures, one has but to realize that, if conditions in this area had been the same as those existing in Indiana, for example, there would have occurred 60,526 cases instead of a mere 479. Or, to put the matter in another light, if the 29 states with higher prevalence had been as active in their efforts to control the disease as were those of the North Atlantic Seaboard, there would have occurred only 860 cases instead of 43,361.

This condition is clearly indicative of the efficacy of vaccination as a preventive of smallpox. Where vaccination and revaccination are neglected, smallpox flourishes; in communities that are well protected, cases and deaths are rare, indeed.—Met. Life Ins. Co., *Stat. Bull.*, 12: 3-5 (May), 1931.

The Homicide Record of 1930 in the United States—During the last 31 years, the homicide death rate for 31 American cities with a collective population of nearly 25,000,000 in 1930 increased from 5.1 per 100,000 in 1900 to 10.9 in 1930. The rate during this period reached a first maximum of 11.3 in 1925, which is the highest figure on record or a little above the record for 1930. The homicide death rate for 147 cities which in 1930 had a population of over 39,000,000 increased from 10.4 per 100,000 in 1929 to 11.0 in 1930, the rate increasing in 73 cities, decreasing in 61, and remaining the same in 13.

The rates for individual cities in this group show wide variations. There were none in Lawrence, Lynn, Manchester, Pittsfield, Quincy, Salem, Somerville, Fitchburg, Gloucester, and Holyoke, Mass.; nor in Lincoln, Neb.; Newport and Pawtucket, R. I.; Union

City, N. J.; nor in Elmira and Mount Vernon, N. Y.

In 14 cities, which report comparable records for 1928, 1929 and 1930, the homicide rate exceeded 30 per 100,000. Of these, 12 are in the South, repeating in many cases the extremely high homicide death rates in that part of the country.

The highest rate for American cities is maintained, as usual, by the city of Memphis, Tenn., the rate having been 58.8 per 100,000 for 1930 as against a rate of 51.6 for the preceding year. With regard to Memphis, the fact must not be overlooked that the exceptional hospital facilities of that city attract patients from the surrounding country, which tends to exaggerate the local homicide death rate. But even when allowance is made for this fact, on the basis of a careful study of residents and nonresidents, the local rate still continues extremely high. During the year 1929, for example, out of 127 deaths from homicide in Memphis, 74 were residents and 53 nonresidents, making the death rate for residents in Memphis 30.9, or approximately three times the general rate for American cities. The next highest rate, 52.6, is for Atlanta, Ga., followed by Lexington, Ky., with a rate of 52.4.

In the 5 largest cities of the country, the number of homicides increased from 1,333 in 1929 to 1,425 in 1930. In

these cities, the highest rate for 1930 (14.4 per 100,000) occurred in Chicago, followed by Detroit with a rate of 13.3; Philadelphia with 7.7; New York with 7.1; and Los Angeles with 6.6. The United States homicide death rate is by far the highest for any civilized country in the world. The rate for Germany for 1927 was 2.0, showing a constant decline since 1920; that for Austria was 3.0; that for Hawaii for the period 1920-1930, 8.5; and that for England and Wales in 1929, only 0.5 as against a rate in the U. S. Registration Area of 8.5 per 100,000 for the same year.

The outstanding crime problem in America imperatively demands drastic restrictions in the sale and possession of concealable weapons. Approximately three-fourths of the murders in the United States are committed by firearms. In the State of Massachusetts, where the firearms law is reasonably well enforced, the murder death rate is relatively low, as shown by the fact that out of the sixteen cities showing no deaths from homicides in 1930, 10 were in Massachusetts. In New York City, out of 219 homicides, 52.1 per cent were caused by firearms; while in Memphis, Tenn., out of 127 homicides, 76.8 per cent were caused by firearms.—Frederic L. Hoffman, *The Homicide Record of 1930. Spectator*, 126: 9 (Apr. 9), 1931.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

A MECHANICAL AID FOR ISOLATING *B. COLI*

E. L. FILBY, C. E., F. A. P. H. A.

Chief Engineer, State Board of Health, Jacksonville, Fla.

IN plating out lactose splitting organisms on eosin methylene blue plates to determine characteristic *B. coli* colonies, the water laboratory of the Bureau of Engineering, Florida State Board of Health, was seldom able to pick up isolated characteristic colonies due to overgrowths. It was suspected that organisms in the water which split lactose after 18 hours' incubation at $37\frac{1}{2}^{\circ}$ C. included *B. coli*, but the problem was how to prevent the overgrowths so that this suspicion could be definitely confirmed.

An old Victor hand wound disk phonograph was obtained and the felt protecting the turntable and centering pin removed. Then a $4\frac{3}{4}$ " diameter "New Daisy" rubber sink stopper was cemented to the turntable at the center. This rubber stopper was shaved down to make a flat resting surface for a petri dish. Next a $2\frac{1}{2}$ " ruby eraser was cut into cubes about $\frac{1}{8}$ " to $\frac{1}{4}$ " high. The petri dish resting on the sink stopper was centered on the turntable and the small cubes cemented to the stopper around the periphery of the dish, allowing about 9 of these guides for 9" of the dish's perimeter and an open space of about 2" for placing and removing the plate. The turntable speed was adjusted to about one revolution per second when the machine was fully wound up.

The procedure of use of this revamped talking machine is as follows: Wind up the phonograph, insert the eosin methylene blue plate, numbering it to coin-

cide with the sample and dilution number, have at hand the fermentation tube and the platinum needle, flame both the

tube and the needle, remove the cotton plug, insert the needle into the fermented broth, reinsert the plug and return the tube to the rack. Then open the brake on the phonograph turntable so that it starts, remove the petri dish cover and hold the broth coated needle at the center of the petri dish for about two revolutions, then slowly push the needle in a straight line toward the edge of the petri dish. In this operation the needle rests lightly on the media without turning. When the needle hits the edge of the plate, lift it, permitting the wrist to stop the turntable, then replace the cover of the plate and remove it.

The needle must have a slight bend

upward at its end so that it will slide over the media as a spoon would. About ten revolutions of the turntable

are made while the plate is being streaked and the time necessary to complete the streak done as above indi-

cated is about 23 seconds. Isolated colonies are easily picked off around the edge of the plate as shown in the photograph. The only disadvantage to this scheme is that a separate plate must be used for each lactose broth portion showing gas.

Dr. Paul Eaton, Director of the Diagnostic Laboratories of the Florida State Board of Health, suggested this idea but it was developed by Lena W. Starck, analyst of the Bureau of Engineering, to such a point that it is now routine procedure. The number of plates positive for *B. coli* as determined by reinoculation of characteristic colonies in the lactose broth has increased considerably over the former results.

The idea of turning the plate mechanically was suggested in the *Journal of Bacteriology* some years ago, but the phonograph is more easily obtainable than the means suggested in that article.

THE BECCARI SYSTEM OF GARBAGE DISPOSAL IN FLORIDA

V. B. LAMOUREUX, C. E., F. A. P. H. A.

Assistant Engineer, State Board of Health, Jacksonville, Fla.

THE Beccari system of garbage disposal originated in Italy some years ago and had its first application in this country at Scarsdale, N. Y. Briefly, the system takes advantage of the natural decomposition of organic wastes, this action taking place in closed cells. The cells are usually concrete but may be of brick or vitrified tile. In about 35 to 40 days the garbage which has been placed in a cell has been reduced to an inodorous humus with a loss of weight of about 85 per cent.

The second plant built in this country was at Dunedin, Fla., which was followed closely by a plant at Belleair, Fla. Both of these plants were constructed

after successful experiments with a very small single cell built at Belleair and filled with garbage which included fish-house wastes and an unusually large amount of citrus wastes. Additional plants have also been built at South Jacksonville and Plant City while an experimental cell was built by the National Juice Company at Tampa for the reduction of citrus wastes.

The plant at Dunedin is a 5-cell concrete structure, each cell of standard size 9' x 8' x 6' 6", and holding about 18,000 lb. of raw garbage. Garbage is placed in layers on wood racks 24" center to center. The tops of the cells slope and the entire lid must be lifted to place garbage in the cells. These

lids are necessarily very heavy and are counter-weighted to facilitate lifting. In addition a corrugated iron building houses a grinder and storage for the ground humus. The entire cost of the plant was \$4,500. The former method of disposing of garbage and trash was to burn it and rake the residue over into a pond. The dump cost the city \$24.80 per month for labor and \$30.00 per month for oil and disinfectants. Since the installation of the Beccari plant at the dump, trash is still burned there. However, the monthly cost of operating both the Beccari plant and the dump is \$5.20 per month which takes in all items, including fuel for the gas engine which operates the grinder. The city manager has estimated the cost per ton of humus produced at \$2.62, while the return has been \$22.50 per ton and the demand for it greatly exceeds the supply.

No nuisance has resulted at any time from the operation of this plant. On the contrary fly and rat breeding have been eliminated as well as scavenging by buzzards and the production of odors by burning garbage.

The Belleair plant was adapted to the peculiarities of the community which has a year round population of 250 and a winter population of 2,500. Eight cells were built equivalent to three standard cells. The construction was of vitrified tile and light hatches for charging the cells were built in place of the heavy over-all lids of the Dunedin plant. Likewise the racks in the cell were made of 1" x 3" cypress in place of 2" x 4" strips used at Dunedin. Trash is burned as formerly but with no nuisance as formerly. The amount of humus from this plant is small, about 7½ tons annually, and is used locally for park purposes. A ready sale is found for any surplus.

The South Jacksonville plant is a standard-cell concrete structure, 21 cells in all, serving a population of

5,600. To take care of trash a small incinerator was built at a cost of \$400. Operation costs are about the same as formerly when a dump was operated but the use of oil and disinfectants has been eliminated. A small brick building houses the grinder and motor and provides storage for sacked humus. Trucks are driven on a ramp between the two rows of cells and dumped sideways through steel hatches into each cell. The cells are discharged beneath the ramp. Although there are many houses immediately surrounding the plant, there are no complaints of odors.

The Plant City plant is a 10-cell structure of concrete. This plant uses outside ramps on each row of cells for charging through hatches. The cells are discharged inside the building covering the plant, which also houses grinder and motor, provides storage for humus, and also storage for sanitary department equipment. The cost of this plant was \$7,081.74, complete.

The cell built by the National Juice Company at Tampa was to experiment with citrus wastes including rag and peel. Lime was added to counteract the acid in the waste and the results were excellent.

Generally speaking the Beccari plants in Florida have proved themselves to be ideal methods for disposition of the garbage. The cost is comparable with that of incinerators and the product is salable with the demand exceeding the supply. There are no nuisances from flies or vermin, and the odorless process of decomposition has enabled the cities to place their plants much closer to thickly settled areas with no complaints. The result has been a material saving per ton-mile of garbage hauled and in the cases where this saving has been accomplished, the residents have secured better garbage collections through more frequent service.

The life of tires has been increased materially through the elimination of

roads littered with cans, broken bottles and abrasive materials. The separation of trash and garbage has caused an additional small revenue to the city treasuries through the recovery of junk, bottles, rags and paper which were formerly dumped and burned or buried.

The sale of humus has made it possible for the cities to get some interest on their investments and there is a ready demand for the product which has excellent fertilizer properties. The humus as it comes out of the cells is dry although it retains its original shape and weighs but 15 per cent of the original charge of raw garbage. It is easily ground and when sacked may be stored away without nuisance. A slight odor of ammonia is noticeable when the cells are first opened.

Separation of garbage and trash is essential. This is usually accomplished by an ordinance requiring separation and its enforcement by refusal to pick up unseparated trash and garbage. Vio-

lators are liable to prosecution.

The trash left is readily burned or buried in the open without nuisance and in the case of South Jacksonville, a small, cheaply constructed incinerator takes care of it. No fuel is needed in the operation of the incinerator. The City of South Jacksonville also gives 50 lb. samples of humus to its residents to aid their campaign for separation of trash and garbage.

The first cell was placed in operation in Dunedin in October, 1928, and since that time no nuisance has arisen at any of these plants and no complaint has been made. In closing, it should be noted that in charging a cell it should be closed within 4 days after the charging starts. Otherwise decomposition odors in the cell will create a definite odor nuisance. The cities that have installed these plants are pleased with the results from their plants and the Beccari system has proved worthwhile in each case.

AN UNUSUAL INSTALLATION OF CHLORINE EQUIPMENT

E. L. FILBY, C. E., F. A. P. H. A.

Chief Engineer, State Board of Health, Jacksonville, Fla.

AN interesting and unusual installation of chlorinating equipment has recently been made in Florida by the citrus industry. One of the nationally known dairy companies this season established a plan in southwestern Florida to extract and freeze orange juice. This juice, put up in attractive cardboard containers, is shipped to northern markets under low temperature conditions, where it is distributed to the consumer by milk men on their morning rounds.

Every precaution is taken to insure sterility of the outside of the orange before the juice is extracted. On a conveyor the oranges are passed through

a bath, washed and scrubbed before reaching the juice extractor. In the short period between scrubbing and juice extraction, bacteria, yeast and moulds were found to multiply rapidly on the skin of the orange. To inhibit this growth a final shower of water containing 15 p.p.m. of free chlorine was arranged over the conveyor immediately prior to the juice extraction equipment. The shower is controlled by a float in a constant level box and the chlorine at the rate of 15 p.p.m. is fed by a solution feed chlorinator into the water entering the box. The plant chemist checks the chlorine application at regu-

lar intervals by the orthotolidin test.

This treatment is in keeping with the rest of the plant, where cleanliness is the watchword, and no effort has been spared to insure purity of the prod-

Biological Investigation of the Water Purification Plants of Calcutta Corporation—Numerous complaints led to a proposal for the scientific investigation of the filtered water of the City of Calcutta. Observation and examination of the material collected proved that the source of all trouble was the abundant growth of plant organisms in the storage tanks and filter beds. The general method of the filter works was then briefly described. This showed a tank known as the "New Storage Tank" in the main source of supply of water for the public of Calcutta.

Illustrations and descriptions showed the conditions of the settling tanks, which explains why the filtered water could not be expected to be very clear and healthy. One day, bubbles of gas were observed to burst on the surface of a filter bed, and later this gas was ascertained to be marsh gas. During the rains, the average condition of the water is generally improved, due to the rain water increasing the oxygen content

uct. The results obtained by the chlorination of the outside of the orange have been most favorable and have contributed to an attractive and satisfactory final product.

of the water, and by mechanical agitation of the surface water.

The biology of the plant and animal organisms in the New Storage Tank and filter beds is then discussed in detail. This brings out the fact that the abundance of nitrates and other compounds dissolved in the water led to the rapid development of phytoplankton in the filter beds. The filter beds were also damaged by having holes made in them by members of the animal kingdom as they grew, feeding on the plant kingdom. This showed the two-fold need for the eradication of algal vegetation.

In conclusion, it is stated that in spite of any scientific remedial measure which may be suggested hereafter, for the present as also for the future, the most important factor will be to keep the whole place thoroughly clean and clear.

At the end of the article is given a list of the various Phanerogamic specimens collected during the study.—K. Biswas, Curator, Herbarium, Royal Botanic Garden, Calcutta, India. Abstr. by R. E. Reinke.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M.D., PH.D., AND LEONARD GREENBURG,
M.D., PH.D.

Handbook of Labor Statistics, 1929 Edition—This is the second handbook of labor statistics to be published by the Bureau of Labor Statistics. The first handbook (*Bull. 439*), issued in 1927, sought to bring together in convenient form for reference purposes digests of the material published by the bureau prior to the year 1927. The present handbook supplements the former one by presenting similar digests of the material published by the bureau in the years 1927 and 1928. Thus, the two handbooks, used together, constitute a convenient abbreviation of practically all the published work of the Bureau of Labor Statistics of sufficiently recent date to be of present-day interest. The material presented in these handbooks represents in large part the original work of the bureau, but this is by no means entirely the case.

Pages 249–285 are concerned with industrial accidents, from the statistical as well as the exposure point of view, including a number of principal industries. The chief interest to us here, however, is the valuable section on industrial health, pages 287–405. Here, federal agencies concerned with problems of industrial health and a review of recent studies of industrial diseases and poisons, morbidity and mortality statistics, legislation, health and working conditions comprise the topic headings. There is a further section on industrial home work, pages 407–437.

Dangerous trades and industries, industrial poisons and other hazards, and most of the chief occupational diseases of current interest are represented by special articles, usually synopses of the originals, accompanied by the proper

references.—*Bull. 491*, Miscellaneous Series, U. S. Bureau of Labor Statistics, Washington, 914 pp. with Index (Aug.), 1929, price \$1.00.

Dangers in Refining Radioactive Substances—It is hoped that this and similar investigations may lead to the removal of all dangers involved in the handling of unsealed radioactive substances. In a series of decomposition products of radium and mesothorium the principal sources of danger ordinarily present are the gamma radiations (particularly radium C, mesothorium 2, and thorium C") and the radioactive gases in the atmosphere (radon and thoron).

Ten micrograms of radium deposited in the body is probably the tolerance limit of the average person. The electroscopic examinations give a timely warning of danger, far more sensitive than any other method. Since the blood of the workers employed in the refining processes described showed no abnormality (the abstractor is hardly inclined to believe this after an inspection of the tables of blood counts of 3 workers employed in the mesothorium laboratory), it is concluded that the exposures have produced no injury to the blood-forming organs. None of the workers (5 in all) has experienced any debilitating effects.

Inasmuch as the precautions now taken are far in advance of those formerly taken, going back for over a period of 10 years after ceasing work, it is concluded that exposure to dangerous radiations may be reduced to a negligible extent, at least where the exposure period is not over 2 or 3 years.—

Herman Schlundt, William McGavock, Jr., and Mildred Brown, *J. Indust. Hyg.*, XIII, 4: 117-133 (Apr.), 1931.

The Toxicity of Certain Benzene Derivatives and Related Compounds

—The outstanding pathologic picture seen in animals poisoned with the various benzene derivatives was a tendency to extravasation of blood in the lungs. A considerable number of benzene derivatives were investigated. With most of the preparations the toxicity was rather low. There is very little danger of accidental poisoning in industry with any material having a minimum lethal dose of over 0.25 gm. per kilo, or 17.5 gm. for a man weighing 70 kilos. Even with limits under that point but over 0.1 gm. per kilo, there is little danger in handling the preparations if thought and reasonable precautions are given to the matter. Personal idiosyncrasy must be kept in mind however. Also that fat soluble or lipid soluble materials, if water insoluble, may poison by skin absorption in doses not toxic by mouth.

It must be emphasized that the toxicities here reported refer only to administration of solids or liquids by mouth. Some of the substances may be decidedly more toxic, however, by skin absorption, and also through inhalation. Therefore these results do not necessarily represent the hazards of industrial exposure to vapors or to skin absorption.—Henry Field Smyth, *J. Indust. Hyg.*, XIII, 3: 87-96 (Mar.), 1931.

The Reduction of Mine Air Temperatures—Authors' summary—

Various methods of obtaining a cooler atmosphere in mines have been mentioned, and an experiment in local air conditioning by means of artificial humidification has been described.

The air conditioning was tried on a coal face 170 yards in length, and the effects of humidification were ob-

served when the apparatus was placed (a) 120 yards away from the face, and (b) close to the face. In the former case the conditioning reduced the air temperature by 7°, but the temperature rose quickly, and by the time the coal face was reached it was only 2.1° lower than under normal conditions. With the apparatus working close to the coal face the air reached the face 7.8° cooler than under normal conditions, but after traversing 35 yards of face the cooling effect was reduced to 1.9°, and further along the face the effect was barely noticeable.

The conditioning caused no sensible rise in the wet bulb temperature.

It is concluded that air conditioning by this method is not likely to be of value for general application, but that it might be used as a palliative measure in certain circumstances.—T. Bedford and C. G. Warner, *J. Indust. Hyg.*, XIII, 4: 135-139 (Apr.), 1931.

“Industrial Health Digest”—This monthly 4-page pamphlet, formerly “The Stethoscope,” began with Vol. I, No. 1, the May issue, 1931, and is to be devoted to especially selected articles and notes of interest to industrial physicians and surgeons. The editor, Dr. C. O. Sappington, Director, Division of Industrial Health, National Safety Council, Chicago, has built up a representative advisory committee and is also giving publicity to the work of the various health committees of sections composing the National Safety Council. The articles or abstracts are all brief and carefully edited.

Pneumoconiosis: The Delayed Development of Symptoms—The authors report 4 cases: (1) Development of symptoms of silicosis 23 years after an exposure of 4 months; (2) Development of symptoms of silicosis 10 years after an exposure of 2 years; (3) Development of symptoms of silicosis 14 years after an exposure of 4 years;

and (4) Development of symptoms of silicosis 10 years after an exposure of 10 years. A number of years of entire freedom from symptoms following the earlier exposure was the case in each instance. Tuberculosis eventually developed in each instance.

The authors point out that most clinical and statistical studies of silicosis have been made on groups of men still employed in dusty trades. From such statistics one cannot say what is the late effect of short exposures.

These instances suggest the necessity of revising the conception of the length of exposure necessary to produce the disease and make it seem probable that after relatively short exposures sufficient dust may be deposited in the lungs to set up a progressive fibrosis, which only after many years becomes sufficiently extensive to produce symptoms. They tend to indicate that men in the work develop symptoms only after many years of exposure, not because that length of exposure is necessary but because it takes a long time for the disease to develop.

—James A. Britton and Jerome R. Head (Chicago), *J. A. M. A.*, 96, 23: 1938–39 (June 6), 1931.

Medico Legal Aspects of Disability in Industrial Lead Poisoning—The present paper concerns prognosis and disability in lead poisoning, and is based upon experiences with over 200 cases observed during the last few years. The details of 12 cases and a résumé of about 90 others constitute the basis upon which the conclusions are reached.

An illustration is given, also, of the dangers of over-confidence in safeguards: a thoroughly modern plant with presumably every known safeguard including physical examinations at frequent intervals and even ordinary illnesses treated by the plant physician, nevertheless resulting within a comparatively short time in a veritable epidemic of lead poisoning in which a great many men were taken acutely ill. "The ex-

planation lies in the very nature of the industry and its inherent hazards."

Industrial lead poisoning is a very costly affair. The annual wage loss attributable to this disease amounts to millions of dollars and the annual total loss to about 5 or 6 times that amount. At present, lead poisoning is compensated, it is thought, in 12 states only, but "the worker still pays the bill in pain and suffering, impaired productive power, workless and wageless weeks and years, and consequent lowered standard of living. It has been estimated that the injured workman assumes from three-fourths to four-fifths of the financial loss attending his incapacity even under the most liberal compensation laws."

Despite the fact that a goodly portion of the lead industry endeavors to avoid payment of compensation for lead poisoning, instead of preventing it and curing when it does occur—as by signing up each employee as an independent contractor, or discharging one dissatisfied race and employing another, or certifying that men ill with lead poisoning were suffering from grippe, influenza, and gastritis—the industry as a whole is willing to coöperate and eradicate lead poisoning from its midst provided it is given the proper incentive and guidance.

That a true case of lead intoxication usually leaves an indelible imprint upon the human system and causes permanent pathologic changes no one disputes. Nor is it denied that poisoning by the same metal may terminate fatally. While Dr. Joseph C. Aub had stated that encephalopathy and peripheral nerve changes may be permanent in nature, but he had no evidence to prove or disprove other organic changes, Dr. E. R. Hayhurst, Dr. Harrison S. Martland, Professor Chayes and Dr. Levin of the Berlin-Lankowitz Hospital (the last two mentioned had made a study of 1,500 cases of lead poisoning), were convinced of other organic changes, as in the kidneys, etc.

After a brief discussion of the organic effects and duration of temporary disability, the author discusses like features of permanent disability. He concludes that about 50 per cent of his cases have cleared up and left no appreciable disability, or have not reached the stage where permanency could be established.

The subjective and objective symptoms of the cases studied, in the order of their frequency, were as follows:

SUBJECTIVE

	Per cent
Persistent headache	70
Dizziness	60
Obstinate constipation	52
Muscle group weakness	48
Premature fatigue	36
Epigastric pains	35
Visual disturbances	33
Arthralgia	32
Shakes	32
Insomnia	20
Periodic vomiting	18
Loss of weight	14

OBJECTIVE

	Per cent
Anemia	60
Eye-ground changes	33
Tremors	32
Unsteady station	25
Hypesthesia and hypalgesia	20
Nephritis	18
Arteriosclerosis (premature)	16
Lead line	16
Cardiac lesions	12
Retinal hemorrhage	11
Facial palsies	10
Dyspnea	9
Wrist and ankle drop	5
Convulsions	2

ability clause to the policy. While this is not conclusive, it is rather significant, in view of the attitude of the insurance companies, who base their opinions on past experience.

Among chief observations were the following: (1) Wrist drop was comparatively rare, with the exception of the painter who used his wrist muscles more than the others; (2) The blood picture is of diagnostic significance in the acute and subacute stages, but is of no import in the chronic stage, which may display a practically normal blood; (3) Persistent headache, dizziness, constipation, general weakness, visual disturbance, muscle and joint pains, in their respective order, are the chief complaints of the patient suffering with chronic plumbism; the other symptoms are just as definite, but less frequent; (4) Clinical pictures and blood findings may vary by industries: white lead workers showed a persistently low hemoglobin, smelterers, a low red blood count; and lead battery workers, arthralgia and myalgia; (5) Workers with chronic plumbism are ready victims for intercurrent diseases, particularly tuberculosis. Incised or lacerated wounds "fester" and the duration of the ordinary cold is out of proportion to its severity; (6) Over-worked men have a longer period of temporary disability and are subject to most residual damage; and (7) The length of exposure was of no material significance. Some men with 2 or 3 weeks' exposure suffered from a more intense attack and were left with greater disability than those with long years of exposure.

CONCLUSIONS

In reply to a questionnaire sent to the medical officers of 30 life insurance companies scattered throughout the United States and Canada we received the advice that a man who had suffered from industrial lead poisoning would not be issued ordinary life insurance and would be "rated" up for a substandard form of insurance. Practically none would issue health insurance or attach a dis-

1. A mild case of lead poisoning may leave no permanent disability.

2. The gastrointestinal type of lead poisoning is of a temporary nature and the resulting persistent constipation is not disabling in character.

3. The cerebrospinal form of lead poisoning is the most distressing in its manifestations, most destructive in nature, most per-

manent in character and may result in total permanent disability.

4. The kidneys usually show the most degenerative changes.

5. Long hours and overwork are conducive to greater disability.

6. Chronic lead poisoning sufferers have a lowered resistance, are poor risks for health insurance, and have a shorter life expectancy.

While the author is not able to produce the legal proof, he feels that once a man suffers from a severe industrial lead intoxication he never completely recovers from it and carries the sequels to the end of his days.—Max Kummel, *J. Med. Soc. of New Jersey* (Apr.), 1931, 7 pp.

Studies on Experimental Pneumonokoniosis. VI. Inhalation of Asbestos Dust: Its Effect upon Primary Tuberculous Infection (Concluded)—The experiments demonstrate that fibrous structures at least as long as 200μ can pass the protective mechanism of the upper respiratory tract and enter the lung. Inhaled asbestos dust does not penetrate to the terminal alveoli of the lung as is the case with a particulate substance such as quartz.

The rate of infiltration of lymphoid tissues in the lungs varies considerably with the animal exposed. Asbestos bodies appeared in the lungs of guinea pigs in approximately 70 days but were not discovered in rabbits after 330 days. These bodies are produced by oxidation and hydrolysis of the chrysotile molecule (of asbestos). They are evidence that the body is capable through chemi-

cal processes of effecting changes in inhaled silicate particles.

Granite dust remains within the pulmonary air spaces and produces no local reaction of fibroblasts for several years, but in the lymph nodes characteristic silicotic nodules develop within 2 years. Carborundum failed to affect the lung tissue even in 4 years, but fibrosis in the lymph nodes was observed in 4 years. Quartz is rapidly concentrated in the lymphoid tissues with a rapid formation of fibrous tissue. Asbestos is concentrated in the bronchioles and their lateral alveoli. Phagocytes carry it into the walls, where fibroblasts are stimulated.

Primary tuberculous infection is influenced only to a limited degree by inhaled asbestos and the tendency to healing by fibrosis was marked; at autopsy 40 per cent of the cases showed healed fibrous tuberculosis. The contrast with quartz dust was marked. Here, in every exposure longer than 5 months, generalized tuberculosis of the lungs and other viscera resulted. In one group of guinea pigs infected with tuberculosis 2 years after the commencement of dust exposure, the localization of tubercles was atypical, while early disease in the spleen and hepatic lymph nodes was the rule. The combined action of asbestos dust and tubercle bacilli in the lung produced more fibrosis than did either agent acting independently.—Leroy U. Gardner and Donald E. Cummings, *J. Indust. Hyg.*, XIII, 3: 97-114 (Mar.), 1931.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Nutritive Value of Potato Protein and of Gelatin—The literature records some instances of continued growth and maintenance on an exclusive diet of potato or potato with both nitrogenous and non-nitrogenous supplements. Relatively satisfactory results were obtained in human beings but the converse in the case of rats. On the theory that the poor results reported were due to a low protein level, experiments were undertaken with potato preparations containing small amounts of starch.

Tuberin contains sufficient amino acids which are lacking in gelatin and which are essential for satisfactory animal growth. The percentage of tryptophane in tuberin is unknown.

A basal diet, used on young albino rats, consisting of a potato preparation, salt mixture, dextrin and cod liver oil, provided 9 per cent of crude potato protein. The potato ingredient was prepared so as to eliminate most of the starch and the product contained 3.48 per cent of nitrogen. On the basal diet the rats maintained their weight for a period of 3 weeks. The addition of 10 per cent commercial casein after extraction with hot alcohol produced immediate growth response which ceased when the casein was withdrawn.

No change resulted after the addition of 4 per cent yeast, untreated, or autoclaved to destroy vitamin A. Ten per cent of gelatin did not make up the protein deficiency apparent in the basal diet. The addition to the gelatin of tyrosine, tryptophane or cystine in combination produced no better results, and growth was not adequate when the

gelatin was increased to 20 per cent. Casein and lactalbumin were fed as 4, 7, and 10 per cent additions to the basal diet.

The experiments indicated no important difference between the proteins on the 7 and 10 per cent levels, but at the 4 per cent level lactalbumin as an addition was superior to casein. The authors conclude that casein and lactalbumin contain an essential dietary factor lacking in the potato preparation and in gelatin and that this factor is not one of the known amino acids.—D. Breese Jones and E. M. Nelson, *J. Biol. Chem.*, 91: 705 (May), 1931.

The Organic Acids of Spinach, Broccoli and Lettuce—The value of acids in food metabolism depends upon whether the acid is easily metabolized, as citric and malic, or difficultly metabolized, as oxalic or benzoic. Certain green vegetables have been examined for oxalic acid and the work here reported was undertaken to include other organic acids.

The spinach, broccoli and lettuce used in this experiment were purchased on the Washington market, and oxalic acid was determined by the method of Arbenz (*Mitt. Lebensm. Hyg.*, 8, 98, 1917). Since no complete analysis of broccoli has been published a complete examination was made and is reported in a table. Spinach was found to contain 0.31 per cent oxalic acid. Citric acid and a small quantity of malic acid were separated by the ester distillation method. The predominating organic acid in broccoli is citric acid. It also contains 1-malic acid and small amounts

of oxalic acid and succinic acids. The analysis shows that the leaves and buds have practically the same composition and nutritive value. Both the buds and leaves contain proteins somewhat in excess of that previously reported in spinach. Lettuce was found to contain oxalic acid, 0.011 per cent, l-malic acid, about 0.065 per cent, and citric acid, about 0.048 per cent.—E. K. Nelson and H. H. Mottern, *J. Am. Chem. Soc.*, 53: 1909 (May), 1931.

Vitamins in Canned Foods. X—The Vitamin Content of Some Common Vegetables—Since the commercial canning of turnip greens has developed considerably during recent years a study was made to compare the vitamin A and C content of this article of food with other green vegetables. The vegetables used were head lettuce (inner and outer leaves), celery (bleached and green), and raw carrots (whole and shredded for 1 to 3 hours before feeding).

Twenty-five mg. of canned turnip greens supplied more vitamin A than 5 gm. of bleached celery and as much as 500 mg. of unbleached celery. They were found to be unsurpassed by any other vegetable and comparable to spinach. Canned turnip greens, head lettuce, and celery are not rich sources of vitamin B. There was found to be more of the B₂ (G) fraction than of the B₁ fraction in canned turnip greens. Head lettuce was superior to celery and canned turnip greens in its content of vitamin B complex.

Compared with canned turnip greens, the vitamin C content of head lettuce, celery and raw carrots was surprisingly low in view of the general belief that raw vegetables are always a good source of vitamin C. Two to 4 gm. of turnip greens gave better growth and less evidence of scurvy than 5 gm. of celery, green or bleached, 10 to 15 gm. of head lettuce, inner or outer leaves, or 10 gm.

of whole or 15 gm. of shredded carrots. —E. F. Kohman, W. H. Eddy, and Celia Zall Gurin, *Indust. & Eng. Chem.*, 23: 808 (July), 1931.

Increasing the Vitamin D Potency of Cow's Milk by the Daily Feeding of Irradiated Yeast or Irradiated Ergosterol—In this experiment, irradiated yeast and irradiated ergosterol were fed and compared as sources of vitamin D for dairy cattle. Twenty-one Holstein-Friesian cows, each producing more than 45 lb. of milk daily on a three-time milking schedule, were selected at random for experimentation. They were separated into 7 groups, each containing 3 cows. Throughout the experiment, which included a preliminary feeding period of 3 months and a supplemental feeding period of 4 weeks, all cows received the same basal ration of alfalfa meal, corn silage, beet pulp and grain mixture.

Group I, or the control group, received nothing but the basal ration and water. During the supplemental feeding period the basal ration of the other groups was fortified with vitamin D obtained from irradiated yeast and irradiated ergosterol.

The cows were exercised at midnight to avoid the sun's rays. Throughout the experimental feeding period, each cow in groups II, III, and IV received 10,000, 30,000 and 60,000 rat units per day respectively of vitamin D as irradiated yeast, while those in groups VIII, IX, and X received 15,000, 45,000 and 135,000 rat units per day respectively of vitamin D as irradiated ergosterol dissolved in relatively small quantities of corn oil.

The vitamin D potencies of the butterfats from the cows in the first three groups were approximately 2, 8, and 16 times respectively that of the butterfat obtained from the control group, while the vitamin D values of the butterfat from the cows in the last 3 groups were

approximately 2, 4, and 16 times respectively that of the negative control. The fact that vitamin D potency of cow's milk can be increased at least 16 times by feeding is important, since milk with its high calcium and phos-

phorus content can be made a still better food. These investigations are being continued and will be published by the authors later.—Byron H. Thomas and Florence L. MacLeod, *Science*, 73: 618 (June 5), 1931.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

The Proposed Committee on Teaching Obstetric Nursing of the White House Conference on Child Health and Protection—In last month's notes it was revealed that a survey by the White House Conference on Child Health and Protection Subcommittee on Obstetric Teaching and Education of Nurses and Nursing Attendants showed that obstetric teaching in schools of nursing has been inadequate. Improvement depends upon improving the conditions affecting teaching of obstetric nursing unfavorably in the nursing schools or devising a way to give obstetric training to large numbers of nurses before they are permitted to care for maternity cases. The formation of a committee was suggested to work on this problem and consider the following:

(a) Studying the preparation in obstetric nursing in those countries where it is considered a postgraduate subject and comparing it with a study of our present methods.

(b) Preparing a fundamental curriculum for theoretical instruction and practical experience in obstetric nursing that will be sufficient to teach nurses what adequate ma-

ternity care is and how to give the nursing part of it from the beginning of pregnancy through the puerperium.

(c) Preparing a plan for securing the approval and gradual adoption of the curriculum by schools of nursing throughout the country.

(d) Preparing a curriculum for postgraduate courses in obstetric nursing which will be supplementary to the fundamental courses and will be planned primarily to prepare experts in obstetric nursing and not to supply additional nursing service for the hospital.

(e) Preparing a plan for securing such courses in certain selected hospitals.

(f) Forming a subcommittee to study the best way to prepare, control, employ, and supervise attendants, nurses' aids, home helps, practical nurses, and others of this type who care for maternity patients.

—The White House Conference on Child Health and Protection. Excerpts from the Report of the Subcommittee on Obstetric Teaching and Education of Nurses and Nursing Attendants, *Am. J. Nurs.*, XXXI, 5: 585 (May), 1931.

The Chicago Conference—Seventeen state supervising nurses, 16 directors of postgraduate courses in public health nursing, 5 presidents (or their representatives) of S. O. P. H. N.'s, and 6 chairmen of public health nursing sections of state nurses' associations—in all representing 26 states—gathered in Chicago in May at a 2-day meeting

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

called and arranged by the National Organization for Public Health Nursing, because of the expressed desire of these groups for an opportunity to discuss their programs and problems with other nurses in like positions and with the National Organization for Public Health Nursing.

There were two general meetings, and the rest of the time the nurses divided into groups for closed meetings. At the first session Dr. Bishop of Tennessee and Dr. Walker, recently of the American Public Health Association, now of the Commonwealth Fund, gave papers; Dr. King of Indiana, and Dr. Harper of Wisconsin, representing the State and Provincial Health Authorities of North America, joined in the discussion.

The purpose and spirit of this conference, which was an experiment, were not to arrive at any weighty conclusions. The results will come through the stimulus of an interchange of ideas and experience between nurses from different parts of the country. Yet each nurse returned home with a new inspiration, a new zest for tackling her own situation, because of this recent contact with others.

All the nurses present concluded definitely that a conference of this kind should be arranged each year; that because of its limitation in numbers, making informality and real interchange possible, it had a value not attainable through conventions.

For the N. O. P. H. N. itself this conference indicated the direction of certain needed services which will help to guide the development of its future program. And it left no doubt, had there been any to start with, as to the interdependence of the national body and these other groups.—N. O. P. H. N. Release, July 1, 1931.

The Frontier Nursing Service—
Six years ago Mary Breckenridge took a two months' horseback trip through

the Kentucky mountains locating the midwives who reported the great majority of the births the preceding year. Later a survey showed it would be energy wasted to try to improve the work of these midwives, who were all grossly ignorant and superstitious and averaged over 60 years of age. Mrs. Breckenridge then took a nurse's training course in New York and a midwife course in London, came back, and started the Frontier Nursing Service, in a Kentucky county in which, for a population of 10,000 people in an area of 50 square miles, there was no resident physician.

The bulk of the cost of the service, the budget for which is \$126,000, is supplied by people from the more prosperous parts of Kentucky through gifts, the remainder from all parts of the United States, and particularly 12 large cities which have Frontier Nursing Service committees.

The service now has 28 nurse midwives, a physician of its own, in co-operation with the state health authorities, with another doctor maintained by a medical mission, and with a dentist for 6 months of the year. The service now extends over an area of 1,000 square miles in the remote Kentucky mountains where there are no railroads, automobile roads or bridges over its rivers and creeks.

There are 9 nursing centers with usually 2 nurses living in each; each nurse has her own district and her work is generalized except that she has had training in midwifery in England besides her public health nursing training. At one center, Heyden, there is an 18-bed hospital and clinic building.

The nurses provide nursing, public health service, and midwifery under medical direction. In addition to the hospital and clinics which are under medical direction the service carries on four types of field work: (1) midwifery, including careful prenatal, and post-

partum care before and after delivery, with a physician called for difficult cases; (2) baby and child hygiene care; (3) bedside nursing care for all ages and ailments; (4) general preventive care coöperating with the Kentucky State Board of Health; under this comes prevention of hookworm, small-pox, etc., chlorinating wells, getting defects corrected among school children, etc.

The nurses all ride horses to get to their cases, and have 33 horses at their disposal. Each nurse has two saddle bags, one in which to keep her general nursing equipment weighing 38 pounds, the other in which she keeps her maternity nursing outfit weighing 48 pounds.

The weight of these is distributed evenly on the two sides of the horse.

The Frontier Nursing Service hopes some time to reach all the isolated and difficult sections of the United States with the same effective work that is being done here in Kentucky. It is not generally realized that from 15 to 20 millions of our population live under frontier conditions in different sections of the country. It is in part because of the poor care available for mothers and babies in these remote sections that 16,000 mothers die in childbirth yearly, and nearly 200,000 babies die at birth or before they are a year old.—Edith R. Solenberger, *Nurses on Horseback*, *Hygeia*, July, 1931, pp. 633-638.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Education-Publicity Headquarters at Montreal—The Committee on Meetings and Publications has set aside a room as a headquarters *for those in any and all sections* who are interested in the spread of information about health activities and education in personal health.

Please write long in advance if you have special material to display.

Copies of printed matter, bulletins, news releases, radio talks and other samples will be displayed in classified portfolios. Address to Montreal Display, Evart G. Routzahn, 130 East 22d St., New York. *Try to send this material during August.* Canadians please note especially.

There will be a table for free samples, *but any taken from the United States should be individually stamped* "Printed

in U. S. A." Will not be passed by Canadian customs unless so stamped.

Dental Hygiene Information Source—The American Dental Association, 58 E. Washington St., Chicago, offers information and materials for educational work according to the following:

The Bureau of Dental Health Education: Offers suggestions and counsel in the promotion of state and community dental health programs. Supplies educational material such as reprints, lectures, talks, posters, slides and films to dentists, hygienists, teachers, nurses and other public health workers. Gives advice and assistance in developing talks and lectures pertaining to dental hygiene for various types of audiences.

The Library Bureau: Circulates dental books and package libraries to members. (Each package library is a collection of periodical clippings, reprints, etc., on one phase of dentistry; over 200 phases have been covered.) Answers questions regarding dental literature.

The Bureau of Chemistry: Investigates old

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

and new dental remedies as presented to the profession and the public. Furnishes chemical data on "secret" formulas.

Publicity Dictionary—John L. Scott, of *Printed Salesmanship*, Chicago, was asked for some definitions:

About the only really authoritative source I could suggest for the definitions about which you recently inquired would be the dictionary. And common usage has, of course, changed the meanings of a number of them according to the dictionary.

The following definitions are my own personal opinions of the meaning for each one and you may take them for what they are worth:

The booklet, pamphlet and brochure I would group together as all being small books, semipermanently bound, the only differences being that a pamphlet has a self cover, the booklet usually has a cover made of something heavier, and the brochure cover is more elaborate and is generally in the form of advertising display.

A handbill is a single sheet printed on one side only, for personal distribution in various ways—house-to-house, by automobile, on street corners, etc.; and a dodger is a small handbill, and a flyer, a small dodger.

A leaflet is a single sheet and may be printed on one or both sides.

A bulletin is an announcement of news or a periodical publication, as the proceedings of a society.

A circular ordinarily has the four-page letter as a basis and is usually found in varying sizes and folds.

A folder is a circular with at least one vertical fold and two horizontal folds but a great many times it has quite a few more folds than these.

"What's On Your Mind?" at Montreal—How could this be done? Where to turn for information? Why was something done this way instead of that way?

Such questions and others will be asked and answered in a luncheon session of the Public Health Education Section. First attention will be given to questions submitted in writing to the editor of this department.

"I Was Never Invited"—To send material for this department, wrote one health worker recently. Will anyone who feels that way please look at the lower left corner of this page—or the same corner in any issue of the *Journal* for a number of years?

Dominion Readers!—We never get enough material for this department from Dominion sources.

Will Canadian readers please note the references to Montreal in this department, copy them, and pass on to local, provincial and Dominion health agencies—public and private?

How to Get Copies—Single copies of most of the publications mentioned in this department *may be secured by writing to the agencies to which they are credited*. Do not expect a city agency to supply free copies for distribution in another city, or a state department to furnish quantities for use in another state.

Usually return postage should be enclosed to private agencies. Although a price is quoted on government publications, in many cases single free copies will be sent if one writes direct to the responsible department or bureau.

Prize Awards for 1931—The Social Work Publicity Council awards include a number of health agency winners:

Envelope enclosure: To Henry Street Nursing Service for a blotter used in raising funds for summer camps.

House organs for lay public: Honorable Mentions to Sunnyslope Sanatorium, Ottumwa, Iowa, and State Charities Aid Assn., New York.

House organs for the staff: first award to Bergen County Tuberculosis and Health Assn., Hackensack, N. J.

Industrial posters: first award to National Tuberculosis Assn. (See under Posters.) Honorable Mentions to the same and to State Charities Aid Assn., New York.

The above and other specimens will be shown at Montreal in September.

Reasons for the awards are given in *News Bulletin*, Social Work Publicity Council, New York, June, 1931.

Please Tell the Editor—Please tell the editor of this department of your successes or failures in getting copies of materials mentioned on these pages from month to month.

Also tell us if you get requests for copies of your publications when they are mentioned in this department.

Newspaper Men Are Like That—A business concern reminds its local branches:

Some newspapermen are hard to get along with. The majority are not. Their average amiability and reasonableness is as high as any business or profession in the world. They don't like servility; they don't like arrogance; they don't like fake. They are brought up in a school which teaches them, as a first lesson of their trade, to spot all such hokum whenever they see it.

Treat your newspapermen respectfully, friendly, honestly, and they will treat you the same way.

A Health Parade in China—June 7 the *New York Times* announced plans for an anti-cholera parade in Shanghai:

The gigantic parade will be a lurid affair, and in an effort to attract the attention of as many hundreds of thousands of persons as possible many kinds of noise will be utilized. Brass bands, drums, a fife and drum corps, gongs, wailing Chinese violins, and even an airplane mounted on a truck with the engine going as loudly as possible will announce the parade's approach and passing.

This hullabaloo is designed to arouse the interest of apathetic Chinese, to instruct them by example on how to avoid the spread of cholera, and to teach them basic ideas of cleanliness in handling food and the ordinary safeguards of decent sanitary measures.

Banners and floats and 1,000 young students shouting through megaphones will emphasize that unclean water, unclean food, unclean fingers, flies and filth are the agencies through which cholera is spread. The coffins will be

labeled as though they contained the bodies of men or women who contracted cholera because of carelessness, and the stuffed dummies on the stretchers will be similarly placarded.

Is it possible that we have become too sane and respectable in attempting to stir "apathetic" Americans—about the rising tide of automobile accidents, for example?

Welfare and Relief Mobilization—This is the title of the inter-community money-raising effort in 370 cities to be conducted, largely under the auspices of community chests, October 19 to November 25, 1931. It is hoped that the campaign will reinforce the efforts of public and private health and welfare agencies to obtain public appropriations and private contributions for two objectives: first, to maintain present activities, and second, to meet conditions growing out of the unemployment situation. Nationally promoted as a coöperative effort, yet it is wholly local in management and in use of funds to be raised.

The central committee invites ideas for promotion and publicity. Statements as to effects of the depression on health are requested. Address Bart Andress, Association of Community Chests and Council, Graybar Bldg., New York. Also send copies of anything you have issued touching hard times and health conditions.

HONORABLE MENTION

To Tennessee Department of Health: for biennial report with table of contents; for the chapter reporting on health education.

MAGAZINE ARTICLES

"The Family Doctor," editorial. *Saturday Evening Post*. July 4, 1931. We need the doctor; what he needs.

"Fewer and Better," editorial. *Collier's*. June 20, 1931. The new birth rate.

"The Hazard of the Automobile," by

Dr. J. A. Tobey, 350 Madison Ave., New York. Reprint from *Scientific Monthly*. June, 1931. *Free*.

"How to be Happy though Vacationing," by L. Clendening, M.D. *Collier's*. June 27, 1931. How to survive vacation—and accidents.

"Is Advertising Honest?" by T. S. Harding. *Nation*. May 20, 1931. Foods, tooth-pastes and "cures."

"Over a High Health Hurdle," by S. G. Blythe. *Saturday Evening Post*. June 6, 1931. Why long life after 63.

"Summer Health Sense," by G. F. Alsop, M.D. *Woman's Journal*, 171 Madison Ave., New York. 25 cents. Also "Birth Control: Yes or No?" by D. D. Bromley. An attempt to state both sides.

"Sunburn—Friend or Foe?" by W. B. Long, M.D. *New York Herald-Tribune Magazine*. July 5, 1931.

"The Swallowed Watermelon," by S. Kerr. *Saturday Evening Post*. May 30, 1931. Yes, it is about health, food fads, etc.

"Take Deep Breath," by H. Durham. *Collier's*. June 20, 1931. "Most of us are only half-aired."

"Too Much Health Advice." *Literary Digest*. June 27, 1931. Copied from *Journal of Indiana State Medical Assn.* "The housewife caught in a maze of vitamins, calories, carbohydrates, and 'acid-producing' foods, and does not know which way to turn."

"Vacation in the Backyard," by M. Fleming. *New York Herald-Tribune Magazine*. July 15, 1931. How to use \$25.00.

POSTERS

Few health posters are truly "posters." In contrast with the many illustrated charts or placards is the new series of 4 issued by the Nat'l Tuberculosis Assn., 450 7th Ave., New York, and available through all tuberculosis associations. Three are devoted to the theme of general health, and may be classified as appeals to children, youth,

and adults (although each may be used for any age group); the fourth is a specific message about tuberculosis to working men and women. 15" by 22"; 4 to 7 colors. *Free folder with black and white copies*. (See Prize Awards.)

Unusually well done is the set of 8 "Child Feeding Charts" prepared by the Bureau of Home Economics, Department of Agriculture. 25 cents a set from Supt. of Documents, Washington. Photographs and limited text; black on white; 15" by 23"; illustrate good food habits and effects of good nutrition. Fewer capital letters in text below the pictures would have increased legibility.

We hope to display at Montreal a group of the health and safety posters issued by the Western Electric Company under the direction of R. T. Barker. It is understood that samples are *not* available.

"Posters and Their Making," by Agnes Smith. *Public Health Nurse*. Sept., 1930. Tells "how a set of 10 posters on health for elementary grades was brought to completion." Emphasizes that—

... if the poster is to be really effective the picture should be so simple that all who see the poster can understand the message without the necessity of any wording. If the maker is sure that this goal has been achieved, then it is quite permissible for a few short words to be added for emphasis, but they cannot be depended upon for the interpretation of the idea. It must be self-explanatory.

NEW

The Playground, 315 4th Ave., New York, is now *Recreation*. New inside and out.

The Public Health Nurse, 450 7th Ave., New York, becomes *Public Health Nursing*. The change follows (but is not the result of) 3 months of diverse shades of blue for the cover page. The final choice is worth looking for.

With July, 1931, *Red Cross Courier*, Washington, D. C., changes from a semi-monthly to a monthly publication.

TIMELY TOPICS

A letter from Charlie Chaplin is quoted in a news release of National Society for the Prevention of Blindness, 450 7th Ave., New York. *Free.*

Pittsburgh's Health, Dept. of Public Health, came out with flags and cover-page text in red and blue. "Carelessness is a human trait, not found in dumb animals" introduces summer hazards.

That "Good eyesight is largely responsible for the making of sport champions" is the theme of a radio talk by David Resnick, National Society for the Prevention of Blindness. *Copy free.*

Usable ideas are better than warnings. At least sunburn warning might be supplemented by such positive information as the following from *The American Girl* published by the Girl Scouts:

Girls who like to be brown-haired but not burned have discovered that rubbing themselves with oil before sun exposure will do the trick. Any oil—olive or mineral. If by accident you get a bad sunburn, you should treat it as you would any severe burn. Minor burning or chapping should be treated immediately with a little oil—use a bit of cold cream or cleansing cream before you wash your face. Calomine lotion—a fine powder liquid which you can buy at the drug store—is a cooling, soothing thing to use for summer irritations such as heat rash, bites or mild sunburn.

"Vacation Hazards"—*Safety Education*, 1 Park Ave., New York. June, 1931. A wealth of teaching ideas for elementary and high schools.

"Vacation Typhoid Fever"—*Missouri Public Health News*, State Board of Health. June, 1931. "Highly civilized communities have very little typhoid fever."

"Does Running Water Purify Itself?"—New York State Dept. of Health. April, 1931. Radio talk. *Free.*

Sanitation in summer resorts, fresh air camps, recreational camps, etc., is covered by a series of articles in *Canadian Public Health Journal*, Toronto. June, 1931. 25 cents.

"Tourist Camp Sanitation" edition of *Iowa Public Health Bulletin*, State Dept. of Health. Jan.-March, 1931.

The Dept. of Health, Ontario, offers educational printed matter and advice touching summer resorts and other recreational facilities, and says:

The Department is at all times willing to assist the Medical Officer of Health in the improvement of Recreational Sanitation within his municipality.

"A New Method of Killing Poison Ivy"—*Health News*, New York State Dept. of Health. Oct. 6, 1930.

"Beware Poison Ivy!"—*Ohio Health News*, State Dept. of Health. May 15, 1931. Good brief statement.

"Prevent Poison Ivy Poisoning"—*Health Briefs*, Tenn. Dept. of Public Health. June, 1931. The source and preventives.

"Avoid Ivy Poisoning by Thorough Washing"—*Woman's Page Miscellany*, Cleanliness Institute, 45 E. 17th St., New York. "According to the Department of Agriculture." *Free.*

"Poison Ivy"—*Scouting*, 1 Park Ave., New York. June, 1931. More detailed description; use of iron chloride.

TELEVISION

Right on the job was the New York State Dept. of Health in presenting March 30 what was probably the first television broadcast of health material.

Then on June 1 the New York City Dept. of Health gave the first combination of television and straight broadcast. The broadcast was the first of a series of talks on weight control in which scientific and medical advice on safe weight reduction methods was

explained each Monday afternoon at 4:45 o'clock during June and July. Audiences could see and hear the talks at Aeolian Hall and 4 department stores.

MOTION PICTURES

Now is the time for taking amateur pictures of summer camps for interpretation and promotion next winter and spring. Argument and suggestions will be found in "Cine Selling for Summer Camps," by E. W. Page. *Movie Maker*, 105 West 40th St., New York. July, 1931. *Sample free*.

Making an Amateur Health Movie, by H. E. Kleinschmidt, M.D. National Tuberculosis Assn., 450 7th Ave., New York. *10 cents*. A 21-page mimeographed pamphlet of practical, working suggestions. Says the introductory paragraph:

The silent movie is being elbowed out of the theater—for better or for worse. But as a means of teaching certain subjects effectively and entertainingly, the silent motion picture retains its unique value. Now is the time to capitalize this educational instrument for teaching health. Owners of cameras and projection machines are increasing in number; the amateur movie is growing out of its toy stage and becoming a serious vehicle of expression. Like the use of the typewriter, the brush, or the piano, the technic of the movie is worth mastering. Here are a few elementary helps and hints.

"Deferred Payment," 4-reel film produced by British Social Hygiene Council, is offered by American Social Hygiene Assn., 450 7th Ave., New York. This film, which deals with syphilis in drama form, has the unanimous endorsement of both lay and professional groups as an effective means of informing the public. Sale or rental.

"Fifty Years of Service to Humanity" is a one reel picture designed especially for this jubilee year of the American Red Cross.

American Social Hygiene Assn., 450 7th Ave., New York, offers 7 pictures

(22 reels) in both 16mm. and 35mm. and at reduced prices for sale and rental.

Special service: If you wish one of the following write the number in () on your business card or letterhead and mail to editor of this department. For each number a new card or letterhead. (*No letter needed.*)

(327)—Catalogue of free industrial and health pictures.

(208)—Catalogue of free industrial pictures.

(54)—Health Movies: How to Use Them, by Dr. H. E. Kleinschmidt. Mimeographed memorandum.

(433)—The Silent Film, by Dr. Iago Galdston. Its value: amateur possibilities. Mimeographed memorandum.

(209)—Catalogue of Eastman Class Room Films—Health Subjects.

(210)—Amateurs now have available a new superspeed 16mm. film. Simplifies picture-taking tremendously according to the description in *Movie Makers*

UNEMPLOYMENT

Under "Tea, Coffee, Cocoa and Other Beverages," *Hygeia* (June, 1931) has a paragraph on symptoms of scurvy and pellagra reported in connection with bread lines. (*Copy free*. Address: 535 N. Dearborn St., Chicago.) Health workers will wish to be ready with information together with helpful minimum diet information issued by Dept. of Agriculture, Washington, and other sources.

Mental Hygiene Bulletin (450 7th Ave., New York, May, 1931) tells about a discussion of mental attitudes as a factor in the current economic slump, a meeting called by Illinois Society for Mental Hygiene. *Copy free*.

Balanced Menus for the Modest Budget—Cleveland Health Council, Federal Reserve Bank Bldg., Cleveland, 2-page letter size sheet. Mimeographed. Well done as to content and inexpensive form. *Free*.

RADIO

Have you had a first aid series via radio? A vacation series—with usable suggestions as to where to go and what to do as well as warnings against what not to do? How to dodge poison ivy? How to get sunburn safely? When typhoid inoculation is desirable?

The past winter the radio talks of Canadian Social Hygiene Council were broadcast in French over CKAC by *La Presse*, which also summarized them in its columns.

Manitoba Dept. of Health and Public Welfare reports:

One gratifying result of sending written copies of the radio talks provided by the department, to those who ask for them—is learning about the various uses that are being made of them. A school principal writes that he keeps them in a loose-leaf notebook on the reading table for his high school pupils. The president of a "Parent-Teacher Association" uses them to prepare for the health discussions that are held at every meeting, etc.

The U. S. Public Health Service will present this month a report on health broadcasting at the international conference on educational broadcasting to be held in Vienna. For this report the following questions were put to state and local health authorities:

(1) Does your department issue broadcasts on public health or personal health subjects? (2) How long have such broadcasts been issued? (3) At what intervals? (4) From what stations? (5) What other agencies, such as medical societies or civic organizations, in your vicinity sponsor material on these subjects for broadcasting? Medical societies were asked—What other agencies, such as voluntary health organizations or civic organizations, in your vicinity sponsor material on these subjects for broadcasting?

The *Journal* question, "Do you do anything beyond straight talks in broadcasting?" is answered by Dr. Lila O. Burbank, Division of Adult Hygiene, Mass. Dept. of Public Health:

Our Radio Health Forum is conducted weekly and is not a "straight" talk since the service consists of questions from the public and answers to them prepared by either physicians of the Massachusetts Department of Public Health or other experts not of the department. Usually a foreword on some phase of public health is given followed by the questions and their answers—about 1,400 words in all. Sometimes some of the questions are answered by mail since the queries are not of sufficient public interest to give over the radio. The practical evidence we have that the broadcasts are listened to is the fact that questions do come in to be answered. We are trying, by substituting questions on health and the prevention of disease for those not suitable for the radio, to educate the people to the kind of questions it is within our province to answer.

Massachusetts has been running three weekly broadcasts: Wednesday at 5:20 p.m. a series jointly sponsored by the State Medical Society; Friday at 12:30 p.m. a State House Broadcast, which included a series of 9 talks on Department activities; and the Radio Health Forum Fridays at 4:50 p.m.

Thanks Due the Editor?—The newspaper editor is a specialist in what people will read in a daily publication. Like all specialists he is not infallible, but as a rule he knows.

The short cut to getting health material into newspapers is via better and better copy. Sometimes editors are too willing to help the health movement and actually print material of doubtful reader interest. Thanks be to the editor when he drops that copy into his waste basket.

When our copy fails to appear we may well believe that it was not readable enough, or that it was kept out by one of the innumerable exigencies which arise hourly in a newspaper office. Any newspaper of any significance receives daily several times as much material as it can use.

BOOKS AND REPORTS

Health on the Farm and in the Village. *A Review and Evaluation of the Cattaraugus County Health Demonstration with Special Reference to Its Lessons for Other Rural Areas—* By C.-E. A. Winslow. New York: Macmillan, 1931. Price, \$1.00.

The book is a comprehensive report of the methods and results of a pioneer experiment lasting over 7 years. In this experiment there was an attempt made to extend the facilities of modern medical science to a rural community. From its nature it should be of interest to public health men and to practical social service workers in rural communities. This latter aspect, i.e., social service, also finds treatment.

The book is written from an optimistic point of view, and the author's economics used in computing returns on the investment in public health are orthodox, even if questionable.

For anyone contemplating an attempt to organize a county health program, this book will offer quite valuable guidance, giving as it does, details of organization and describing machinery for a fairly successful attempt as well as pointing probable obstacles.

The first chapter is a good summary of the outstanding lessons of the demonstration.

ALLEN E. STEARN

How the Nurse Can Help with the Cancer Problem—*For Distribution by the New York City Cancer Committee, 34 East 75th St., New York, N. Y.* 30 pp.

This excellent leaflet begins with a consideration of the control of cancer in general, following which there are articles by specialists on cancer of the skin, breast, and uterus. The longest

article is devoted to "The Nursing Care of Cancer Patients." Its source guarantees the accuracy of its contents.

It is distributed free to nurses and interested groups. M. P. RAVENEL

The Vitamins—By H. C. Sherman and S. L. Smith. (2d ed.) New York: The Chemical Catalog Company, Inc., 1931. 575 pp. Price, \$6.00.

The scientific and technologic monographs of the American Chemical Society series are welcomed by chemists and other scientists for their assistance in coördinating and extending knowledge otherwise available only in numerous journals. The vast amount of research, the complexity of the subject, and the diversified character of the chemical nature of vitamins results in a widespread need for a concise, readable, and accurate presentation, which is here given.

The first edition of this monograph covered practically all the important literature on vitamins to the end of 1921. This edition summarizes the knowledge since acquired regarding the chemical nature of the individual vitamins—their rôles in life processes, their formation and distribution in nature, their relative abundance in different food materials, their stability under different conditions, as well as the processes for their extraction and concentration.

Separate chapters are devoted to each vitamin. The book begins with a General Introduction to the Vitamin Theory.

The complex nature of the vitamin originally known as B is discussed in two chapters. The controversy over the two factors now recognized and the

various approaches to the methods of adsorption, extraction and separation are clearly given. That other factors are concerned in the nutrition of mammals, and may be recognized as additional vitamins, is predicted.

The need of vitamin C in metabolic processes is shown in its antiscorbutic properties, and its effect on teeth and bone formation. Only recently have we known of the comparative antiscorbutic values of the different foods. The determination of the protective dose of vitamin C against scurvy is of considerable interest in that it has been found by some workers that the minimum protective dose for the teeth is almost exactly twice that for protection against the more familiar symptoms of scurvy. If it becomes established that this represents the true difference between tooth and general body requirement, the antiscorbutic values need only be multiplied by 2 to change them into tooth protective values.

Observations on disease resulted in the discovery of vitamins B and C. The failure to secure normal growth in experimental animals on purified food materials gave rise to the conception of fat soluble vitamin A. The term vitamin A, in the monograph, covers both the precursor form (carotene) and the form immediately active in animal nutrition. Both land and water plants synthesize the vitamins, and from them, animals, including fishes, derive their supplies. The intensely yellow carotene synthesized in plants is more or less completely converted into the almost colorless vitamin A in the animal body.

The antirachitic vitamin D is a calcium and phosphorus mobilizing factor, and thus exerts a distinct influence on the anatomic elements of the growing bone, but neither it nor ultra-violet light can replace an actual deficiency in these elements. A ration which produces rickets in rats can be rendered anti-

rachitic by exposing it to ultra-violet light. The production of vitamin D by irradiation of ergosterol is discussed.

The recognition of the distribution in plant and animal substances of vitamin E, its function in maintaining fertility, as well as other knowledge about it, are given in the last chapter. This vitamin is found widely distributed in foods, and only a very small amount is needed for its special function.

The authors have succeeded in presenting in concise form, through selection of experimental evidence, the present status of the knowledge concerning vitamins. An excellent bibliography, as well as an author and subject index are appended. ESTHER W. STEARN

Calidad Bacteriologica de las Aguas de Caracas, Venezuela, S. A., y Metodos Modelo Para el Analisis de Agua y Alcanta-Rillado—Seccion Bacteriologica, 1930. Caracas, S. A. 50 pp.

Dr. E. I. Benarroch publishes the results of the bacteriological analyses of the waters of the public supplies in Caracas, Ven., S. A. Although incomplete, as the author states in his paper, these analyses give a thorough idea of the poor quality of water in Caracas. A brief summary in English is published.

The second part is a fairly good Spanish translation of the Bacteriological Section of the *Standard Methods for the Examination of Water and Sewage* (6th ed.), 1925, published by the A. P. H. A.—Some words like "fiola" are not used in pure Castillian and must be changed.

This translation is to be recommended to Latin-American laboratory workers and a complete translation into Spanish of the whole *Standard Methods* is desired.

En un folleto de cincuenta páginas, el Dr. E. I. Benarroch publica los resultados obtenidos de los análisis bacte-

riológicos de las aguas de los abastos públicos de Caracas, Venezuela, América del Sur, con los que, aunque incompletos como el mismo autor lo indica, se puede tener una idea clara de la mala calidad de esas aguas, desde el punto de vista bacteriológico.

La segunda parte del folleto es una buena traducción de la Sección de Bacteriología, de los Métodos Modelo para el examen de aguas y alcantarillado—6a. edición 1925—publicados por la Asociación Americana de Salubridad. En su lectura se encuentran algunas palabras como "fiola" que no son usadas en castellano puro y deben ser cambiadas.

Este trabajo es de recomendarse a los laboratoristas latino-americanos y es de desearse una traducción completa—de los Métodos Modelo que ayudará a la unificación de los procedimientos de análisis de las aguas.

A. DE LA GARZA BRITO

The Home Care of the Infant and Child—By *Frederick F. Tisdale, M.D.* New York: *William Marrow & Co.*, 1931. 292 pp. Price, \$3.00.

This is a very attractive and well conceived book in which prenatal and infant care are combined in the one volume. Modern procedures, based upon the scientific work of the last two decades, are set forth in simple understandable language for the average mother.

The book is printed so as to be accessible for ready reference. Each topic is treated with just enough fullness to be explicit, but is not overdrawn. Excellent illustrations add to the practical value of the book. The first three parts deal with prenatal and neonatal care, the care of the baby during the first year of life, and care of the older child.

A feature of this book which should prove especially helpful to mothers and fathers is the last section dealing with special problems such as accident prevention, behavior problems, and the play

life of the child. This book is recommended to parents who desire definite, scientific consideration of their children's health problems. R. A. BOLT

First Aid for Boys—A Manual for Boy Scouts and for Others Interested in Prompt Help for the Injured and the Sick—By *Norman B. Cole, M.D., and Clayton H. Ernst.* (rev. ed.) New York: *Appleton*, 1931. 192 pp. Price, \$1.50.

This is an excellent guide for Boy Scouts as well as older persons. It is written in language which is easily understood and the directions for first aid are sufficiently clear to be understood by all.

It can be commended for its announced purpose. M. P. RAVENEL

Untersuchung der Nahrungs- und Genussmittel. Allgemeine Methoden—By *Dr. Wilhelm Plücker.* Berlin: *Urban & Schwarzenberg*, 1931. 1046 pp., 295 figs. in text. Price, bound, M. 59.

Tabellen- und Rechenbuch für Nahrungsmittelchemiker. By *Dr. Wilhelm Plücker.* Berlin: *Urban & Schwarzenberg*, 1931. 231 pp. Price, bound, M. 22.

These two works which are also incorporated in *Abderhalden's Handbuch der biologischen Arbeitsmethoden*, Abt. iv, Teil 14, cover the field of food chemistry in an exhaustive manner. The entire field is covered except the determination of molecular weights and the detection of preservatives, treated elsewhere in the *Handbuch*. The opening sections deal with general procedures. Biological methods follow, including the detection of arsenic, the precipitin reaction for honey, and serological methods in the separation of cereals, vegetable oils, horse fat, and the various sugars. The chemical methods elaborated in great detail are concerned with the volatile oils, al-

cohols, aldehydes, ketones, esters, and acids, with the amines, amino acids, albumins, nitrogen-free extractives, coloring matters, fats, carbohydrates, lipoids, mineral matters, rarer bases and acids, and water determination. The physical methods discussed include agitation, extraction, colorimetry, distillation, dialysis, decolorization and clarification, extraction of solids, filtration, fluorescence, freezing point, critical solution temperatures, conductivity, microanalysis, nephelometry, solubility, polarization, refractometry, spectroscopy, crystallization, determination of melting and boiling points, specific gravity, ultrafiltration, viscosity, and hydrogen ion concentration.

There are lists of reagents for the various fields of analysis and a very fully worked out book of tables and computations for the many types and forms of analysis.

The work is up-to-date, gives the pros and cons for alternative methods, and suggests fields in which improvements in current practice are needed.

CHARLES A. KOFOID

Correction: In June *Journal*, page 704, a review of *Facts and Figures About Tuberculosis* stated that the book was published by the New York Tuberculosis Association. This should have been National Tuberculosis Association.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Baltimore, Md.—This city, with an estimated population in 1929 of 841,728, records a birth rate of 16.6, the white rate being 15.1 and the negro rate, 25.2. The total death rate was 13.8, that for the white being 12.2 and for the colored, 23.1. Comparative data for births, deaths, and for specified causes of death, by color, are given for previous years. In 1929, a tuberculosis death rate of 79 was recorded for the white, as compared with 316 for the colored population.

We have found it very profitable in our health work not only to carry the advantages of education to the public as a whole, but also to our working forces in the field. The response, by the workers in the several bureaus where Book and Journal Clubs have been formed, has been highly gratifying to their chiefs as it has not only benefitted the field worker but also the directors themselves by increasing their breadth and depth of views of their own special ties.

The laboratory reports indicate that several special investigations of a research nature were conducted, as well as routine work.

In connection with a diphtheria immunization campaign, it is noted that two circular letters were addressed to physicians asking for their coöperation and suggesting that the health department supply the toxin-antitoxin. Communications were sent to all life insurance companies to encourage them to have their agents speak to parents about the procedure. Over 140,000 pamphlets *Your Child Looks to You for Protection* were placed in the hands of the Police Department and were distributed by them in homes in the city. The trolley cars placed T-A-T sign cards in every car to go with an article by the health officer and a list of clinics in *Trolley*

News. Immunization clinics were organized and their work was followed up by a Schick team of physicians.

Brookline, Mass.—In the 1930 annual report, a population of 47,730, a birth rate of 11.2, and a death rate of 11.88 are noted. Deaths from heart disease lead the list of causes of death, and number 28 per cent of the total. There were 16 cases of diphtheria, but this was the seventh consecutive year with no deaths from this cause. Of 644 school children Schick tested, 43 per cent were found to be immune to diphtheria, while 467 children previously given toxin-antitoxin were re-tested and 63 were found to be still susceptible and were again given the protective inoculations. In addition, 132 infants were given toxin-antitoxin at the community health center.

There were 17 deaths from tuberculosis with 28 new cases reported (62 in 1929). At 87 clinic sessions, 640 chest examinations were made of 249 individuals of whom 111 were new patients. There were 2,718 home nursing visits made in behalf of tuberculosis cases.

A health bulletin of a popular character is published quarterly and distributed by the Police Department to every house in town. This bulletin serves to inform residents of the quality of milk sold and gives publicity to various health activities conducted in town.

Pittsfield, Mass.—This city of 49,677 population presents an interesting health department report which shows an infant mortality rate of 40.5 for 1930. During the year the Chadwick Clinic made possible the examination of over half the school children, the

Von Pirquet test preceding the X-ray and physical examination. Cases of hilum tuberculosis thus found are sent as rapidly as possible to Westfield for treatment. All retail raw milk, as well as milk for the largest pasteurizing plant, is obtained from tuberculosis free herds. The activities of the health department have been rated by the health officer on the *Appraisal Form* of the American Public Health Association. and show a weighted score of 776 points.

New Jersey—For the fiscal year ending June 30, 1930, the New Jersey Department of Health reports the lowest annual case and death rates from typhoid fever on record for the state, together with an absence of large outbreaks of communicable diseases. There were 16 cases of typhoid fever traced to raw milk. One member of the dairyman's family, who bottled the milk, was found to be a carrier.

Public health services included bacteriological examination of 65,987 specimens for physicians and health officials, an increase of 10 per cent over the previous year. Nearly half of these specimens were for the Wassermann test for syphilis. Diphtheria prevention in rural communities depended largely on the assistance of the department in organizing clinics, arousing public interest, and in giving Schick tests after the toxin-antitoxin treatments were administered by local physicians. There were given in this manner Schick tests to 10,144 persons and toxin-antitoxin to 5,558 individuals. Nurses reporting to the department assisted in giving toxin-antitoxin to 16,465 school children and to 11,388 preschool children.

Transition from policeman to teacher has affected both the work and point of view of health officials. So true is this that nearly every activity of the State Department of Health attempts more or less directly to instruct, interest and lead local officials and citizens to do the right thing for their own well-being and that of their neighbors.

New Britain, Conn.—On the basis of a population of 69,000, a death rate of 8.4 is calculated for 1930. Of 88 infant deaths (rate of 66.6) 50 were among infants under one month of age. A health department expenditure of \$.51 per capita is noted. The health officer recommended in his annual report the transfer of garbage collection from the health department, and the inauguration of a diphtheria immunization campaign. The public health laboratory showed an increase in examinations of 38 per cent over the previous year.

Schenectady, N. Y.—An infant mortality rate of 46, much lower than usual, is reported for 1930. Based on a population of 95,652, a general death rate of 11.2 is recorded. In contrast with last year, there has been a falling off in the amount of milk and cream sold in the city. This is believed to be largely due to the depression. A congenital clinic is maintained, to which 11 first visits and 79 revisits were made. Attendance at the tuberculosis clinic numbered 1,228. Other clinic services included prenatal, child hygiene, cardiac, and dental. Among the health officer's recommendations are noted expressed needs of a health education director, a social service worker at the health center, and improved facilities for the care of mental disease cases.

San Diego, Calif.—Tuberculosis control activities among dairy herds, under the supervision of the State Department of Agriculture, resulted in the testing of 12,567 animals. There were 85 reactors to the tuberculin test. A new milk ordinance was passed providing the same standards from outside dairies supplying San Diego as from those in the city and county.

On the basis of a population of 149,423, a birth rate of 16.9 and a resident death rate of 11.1 are reported. The infant mortality rate in 1930 was

49.3. There were 74 deaths in the city resulting from automobile accidents. Of this number 57 were from accidents which took place within the city limits. There were 1,384 personal injuries resulting from motor vehicle accidents occurring in the city, as compared with 1,042 the previous year.

The California school code requires that instruction be given in elementary and secondary schools on the subjects of public safety and accident prevention. A 195 page book, *Course of Study in Safety Education*, published by the automobile club of Southern California, is used in this connection.

Edmonton, Alberta—Edmonton reports for 1930 a general death rate of 6.8 and an infant mortality rate of 48.9, both low records. Cancer was the leading cause of death with heart disease and tuberculosis following in order. This city of 80,000 people reports only 9 cases of diphtheria, with no deaths from this disease, "an outstanding proof of the value of the diphtheria prevention treatment carried out in recent years."

A summer camp was organized by the Kinsmen's Club for childhood contacts of tuberculosis cases, and a graduate nurse was in charge of the six weeks' camp. Under the direction of the Provincial Department of Health, 2 child welfare clinics were held weekly with an attendance of 5,286, an increase of over 600 over the previous year. A course of 16 lectures on public health topics was arranged for the benefit of the staff and others. This report contains an excellent organization chart showing the community health services.

Prevention of Blindness—The co-operation of a wide diversity of organizations throughout the United States in the steadily expanding movement to prevent blindness and conserve vision is emphasized in the sixteenth annual

report of the National Society for the Prevention of Blindness.

The society realizes more than ever that it can function completely only when it is working closely with all agencies interested in any aspect of saving sight—medical, educational, social welfare, and industrial.

It has been the constant aim of the society to encourage and participate cooperatively in the field of research into the causes of blindness. Among the major causes are glaucoma and trachoma, both of which, it is felt, can be appreciably reduced.

Continuing the study undertaken in coöperation with the Massachusetts Eye and Ear Infirmary and Harvard University Medical School on the effect of adequate social service follow-up in connection with glaucoma patients, the number of glaucoma cases now registered in the clinic at Boston is perhaps greater than ever registered in any glaucoma clinic. There has been also a continual demand for the society's special pamphlet on glaucoma.

The granting of \$250,000 by the Commonwealth Fund permits Washington University, St. Louis, to undertake study of the etiology and control of trachoma. It is felt that once the real cause of trachoma is definitely established, it will be possible to wipe out a great cause of blindness which affects almost every country in the world. The society is called into consultation with those working on the trachoma problem, and there is a constant demand for its literature.

As part of its White House Conference project, the society compiled information and statistics on existing legislation providing special classes for conserving the sight of school children and offering financial aid for their maintenance. A special report was given to the Sub-Committee on Special Classes for Education of the Blind and Partially Seeing Children, on all phases of sight-saving classes—growth, health of the pupil, methods of administration, supervising, teacher training and vocational guidance.

The formulation of a "Program for 100 Per Cent Eye Protection in Industry" has been begun. This, when it has been completed, will be presented in the form of a self-appraisal for safety engineers and other executives concerned with the conservation of vision in industry. It is the opinion of the society and of numerous safety engineers consulted in the matter that such a program intelligently and conscientiously applied to even the unusually hazardous industries will help considerably to eliminate industrial eye

accidents, one of the most serious causes of blindness.

During the year, through the auspices of the Medical Social Service Section of the Welfare Council of New York City and the Associated Out-Patient Clinics, a committee on development of social service in eye clinics was formed. This committee, of which several staff members of the society are members, arranged a series of study conferences on eye diseases and defects of especial interest to medical social eye workers.

In conjunction with the American University at Cairo, Egypt, the society sponsored a two-reel motion picture which points out the importance of care of the eyes early in life, treatment of trachoma, and methods of protection against industrial eye hazards. It also assisted the Near East College Association by preparing a complete set of exhibit material for a health education program in Syria.

The report indicates a continued reduction in the amount of blindness resulting from ophthalmia neonatorum, usually called "babies' sore eyes," and attributes this to the use of prophylactic drops in the eyes of babies at birth, as required by law in most states. The number of "sight-saving" classes for school children with defective vision has grown to 375, but several thousand more are needed.

Approximately 500,000 of the society's publications were distributed during the year, staff members lectured in more than 100 cities in 21 states, and nearly 25,000 letters were sent in answer to inquiries from all parts of the country regarding a large variety of technical and general problems connected with the preservation of good eyesight.

Trenton, N. J.—Credit is due this city for a carefully prepared and well printed annual report for 1930. Among the outstanding developments of the year are noted the establishment of a mental hygiene clinic, the promulgation

of a new ordinance regarding the sale on the streets of certain manufactured foodstuffs, and a provision for the reporting to the Health Department by physicians of persons bitten by a dog, cat, or other animal in connection with the state act for the "Prevention and Control of Rabies."

Up to the end of 1929, the Schick test was given to 12,571 public school children. Of this number, 6,571 were inoculated with toxin-antitoxin, 6,151 gave a negative reaction, and 1,843 were treated without having been previously Schick tested. Of 1,235 previously treated children who were re-Schicked, 1,046 gave negative reactions. Another group of 3,701 previously treated school children were re-Schicked and 2,915 gave negative reactions. In addition, 4,153 parochial school children have been given toxin-antitoxin. This report is well illustrated with statistical tables and charts.

Marion County, Ore.—Following an organization chart and a personnel statement, the 1930 report of the Marion County, Ore., Department of Health lists in a comprehensive manner 15 community health services. An effective cut from the A. P. H. A. *Syndicated Health Bulletin* with the caption, "Ounces of Prevention," directs attention to the economic losses due to illness which may be prevented.

For the calendar year, the lowest infant mortality rate for the county (36.4) is recorded, together with an increase in the number of young children protected from diphtheria, the passage of a modern milk ordinance for Salem, marked improvement in venereal disease control, and an honor rating for Salem in the Inter-Chamber health conservation contest of the U. S. Chamber of Commerce. This report of 23 pages illustrates the value of good headings and subheadings and careful preparation.

Kansas—The 15th biennial report of the State Board of Health of Kansas for the period ending June 30, 1930, opens with an organization chart showing the official activities and listing 6 cooperating agencies. Several charts and reproductions of health posters awarded prizes in the high school contest add interest to the report. The diphtheria eradication program has resulted in the administration of toxin-antitoxin to not less than 340,000 children besides an estimated number of 110,000 protected by private physicians. A change in deaths from diphtheria by age groups is noted for a period of years, 68.6 per cent in 1928 being in children under 10 years of age as compared with 80.7 per cent for the 10-year period 1916-1925.

The lowest death rate from tuberculosis of 35.1 was recorded in 1927, and the second lowest of 38.2 in 1929. The Health Department and Other Reports second lowest infant mortality rate of 57.3 was recorded in 1929, the lowest rate, 54.1, having been noted in 1927. At the close of the fiscal year 1930, 11 counties in the state were operating under the plan of full-time health protection. Two schools for health officers and public health nurses were held during the reported period. These were made possible through the cooperation of the U. S. Public Health Service and voluntary agencies.

Bermuda—A very interesting report of the health and sanitary conditions of Bermuda has been prepared for the year 1930 by the Director of the Medical and Health Department. This report shows that, except for an epidemic of measles,

the year was a reasonably healthy one. Most of the measles cases were mild. There were 54 cases of diphtheria reported, with 9 deaths. Of the total cases, 27 were white persons, and 26 were persons under 18 years of age. In 1929, 1,730 children were given immunizing treatments against diphtheria, and only one of this number subsequently developed the disease. "An outbreak of diphtheria does but half its damage outright. It leaves bacilli tucked away in the noses or throats of its previous victims or of people who have been in contact with them." Emphasis is given to the importance of immunization measures.

There were 8 cases of typhoid during the year, with 1 fatality. In seeking the source, a carrier was discovered. There were 13 cases of tuberculosis reported and 11 deaths from this disease. In the construction program of the King Edward Hospital is a new isolation building which may also accommodate the few tuberculosis cases needing hospitalization.

The population of 31,211 is made up of 16,400 colored and 14,811 white persons. The area of Bermuda covers 19.5 square miles. During 1930, there were 565 births among colored and 224 among white persons, giving a total birth rate of 25.2. A general death rate of 9.99 is recorded, with an infant mortality rate of 76.

Active control measures against the breeding of rats, mosquitoes and flies are described. An active program of health education in schools has been instituted. It is also gratifying to note a movement for several dairies to cooperate in the pasteurization and delivery of milk.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON. PH. D.

Health Status of Negro Industrial Employees—Among a group of 1,000 negro factory workers, over 900 were found to have serious physical defects, and all but 3 would profit by early medical care.

ALLEN, F. P. Physical Impairment Among One Thousand Negro Factory Workers. *J. Indust. Hyg.*, 13, 5: 157 (May), 1931.

The Lubeck Disaster—Was a culture of virulent tubercle bacilli added to the BCG stock, or did BCG recover its virulence under the cultural methods employed in the Lubeck laboratory? This question remains unanswered in what seems to be an unprejudiced review of the regrettable affair. "The moral, however, is plain. The preparation of vaccines for large-scale distribution should be undertaken only under the most rigidly controlled conditions in laboratories set aside for this and for no other purpose."

ANON. The Lubeck Catastrophe. *Brit. M. J.*, 3674: 986 (June 6), 1931.

Refuse Incineration—Fundamentals of furnace design, plant location, and operating procedures are touched upon to serve as a guide to municipalities facing refuse incineration projects.

BARTLEY, R. J. Factors in the Incineration of Community Refuse. *New York State J. Med.*, 31, 11: 679 (June 1), 1931.

Pasteurized Milk and Nutrition—To counteract raw milk propaganda based upon unscientific evidence, this committee quotes several studies which find pasteurized milk the nutritive equivalent of raw milk, and urges the U. S. Public Health Service to settle the question once and for all.

BROWN, E. G. Report of Committee on

Milk. *Pub. Health Rep.*, 46, 25: 1455 (June 19), 1931.

Tuberculosis Prevention Today—Reviewing the newer knowledge of tuberculosis, the author points out reasons for the present-day emphasis on the prevention of childhood infection, the improvement of child health, and to this end, the general betterment of health education.

GALDSTON, I. The Newer Aspects of Anti-Tuberculosis Work. *New England J. Med.*, 204, 25: 1303 (June 18), 1931.

Next Steps in Child Hygiene—Beginning in the field of sanitation, child health has passed through the same stages of development as other health promotional activities, the goal being stated in the findings of the White House Conference.

HAINES, B. M. The Maternal and Child Hygiene Program of the Future. Where and How Shall the Emphasis be Placed? *Pub. Health (Mich.)*, 14, 6: 123 (June), 1931.

Epidemiology of Undulant Fever—Evidence is presented indicating a high incidence of past *Brucella* infections in persons, not in contact with cattle, presumably transmitted by raw milk. Highest ratios were found among veterinarians, farmers and meat packers.

JORDAN, C. F. Infection in the Epidemiology of Undulant Fever in the General Population and in Selected Groups in Iowa. *J. Infect. Dis.*, 48, 6: 526 (June), 1931.

Diphtheria in Two Large Cities—This statistical study of diphtheria mortality rates in Philadelphia and New York shows the 1930 rate in both cities too far below the anticipated level to be attributable to chance. The relation-

ship of rates and age grouping considered in the light of immunization practices is significant.

LEE, W. W. Diphtheria Immunization in Philadelphia and New York City. *J. Prev. Med.*, 5, 3: 211 (May), 1931.

Avoiding Health Nostrums—"In general leave your health alone. . . . You can influence it a little more than you can influence the weather, but not much more. . . . There is no better general guide to food choice than healthy hunger." Why do writers feel called upon to travel the route indicated by these quotations in order to warn against quackery and health nostrums?

LYON, E. P. *Science and Health*. Graphic Survey, 66, 5: 265 (June), 1931.

Why Cancer Clinics?—The opportunities of the cancer clinic made clear for the intelligent public. Well done.

MATTICK, W. L. The Value of the Cancer Clinic to the Community. *New York State J. Med.*, 31, 11: 696 (June 1), 1931.

Faulty Nutrition Results—"Properly fed animals remain remarkably free from disease; improperly fed animals are remarkably subject to it. It is reasonable to assume that the human species is no exception to this rule." Words of wisdom concluding a scientific demonstration conducted at the other side of the world.

McCARRISEN, R. Some Surgical Aspects of Faulty Nutrition. *Brit. M. J.*, 3674: 965 (June 6), 1931.

Body Mechanics—Functional health is greatly influenced by body mechanics and poor posture can be converted into good by adequate training, so says this article.

Streptococcus Studies—A demonstration illustrating the impossibility of separating by available methods the streptococci associated with septic sore throat and scarlet fever into definite groups related to the particular type of infection.

WHEELER, M. W. *Streptococci Associated with Epidemic Septic Sore Throat; Their Relationship to Streptococci Associated with Scarlet Fever*. *J. Prev. Med.*, 5, 3: 181 (May), 1931.

NEWS FROM THE FIELD

BELGIAN CHILDREN ORPHANED BY INDUSTRIAL ACCIDENTS

A LAW recently enacted in Belgium provides for a national bureau for the care of minor children who have lost the support of the family breadwinner through industrial accident. The bureau is directed to supervise in their behalf the enforcement of the child welfare laws, especially the administration of pensions awarded under the workmen's compensation law and of their property in general, to give pecuniary aid or aid in kind when needed; and to watch over their general education and vocational training.

The bureau is to be represented by local committees in the Provinces and cities. Through these committees welfare visitors of suitable education, experience, and character will be appointed to advise the child's mother or guardian and to supervise the child's general well-being. These visitors will serve without remuneration. Women are preferred for the work in the case of young children.—*Oeuvre Nationale de l'Enfance*, Revue Mensuelle, Brussels, Feb. and March, 1931.

FIRST NATIONAL CONGRESS ON SOCIAL SERVICE FOR CHILDREN, ARGENTINA

THE first national congress on social service for children in Argentina will be held in Buenos Aires, September 20 to September 26, 1931.

Its purpose is to study the various problems of child welfare and methods of their solution. Among the subjects mentioned in the program are: Treatment of the defective and delinquent child; effect on child of the mother's employment outside of the home; training of social workers; establishment of

a council of social agencies and of a social service exchange in Buenos Aires.

The president of the congress will be Dr. G. Araoz Alfaro, President of the National Department of Hygiene.—*Boletín de la Oficina Sanitaria Panamericana*, Washington, May, 1931.

POWDERED MILK FOR PORTO RICO

FOLLOWING suggestions by Dr. S. J. Crumbine, Prof. H. C. Sherman, and other scientists, that one of the greatest public health needs of Porto Rico is an adequate supply of American canned milks, employees of The Borden Company of New York have donated 2,700 pounds of Klim Powdered Whole Milk for this purpose. This shipment, equivalent to nearly 11,000 quarts of fluid whole milk, will be distributed to the child welfare stations in Porto Rico. At these stations Klim has been used for infant feeding for more than a year, but lack of funds has recently caused the closing of a number of the clinics.

HOMICIDES IN NEW YORK

THE number of homicides in 1930 in the State of New York, 698, and the rate per 100,000 population, 5.5, were the highest ever recorded. As compared with 1929, the number of homicides in New York City increased from 425 to 494 while in the rest of the state there was a drop from 220 to 204.

AMERICAN HOME ECONOMICS ASSOCIATION

THE American Home Economics Association held its 24th annual meeting, June 22-27, in Detroit, Mich., with an attendance of 1,500.

Among the speakers were Dr. F. J. Kelly, Chairman, Education Section,

White House Conference; Prof. John Sundwall, University of Michigan; Francis C. Davis, Merrill Palmer School; Wells A. Sherman, U. S. Bureau of Agricultural Economics; and Edith Hale Swift, American Social Hygiene Association.

Mary P. Connolly, Director, Division of Health Education, Department of Health, Detroit, attended the meeting as official representative of the A. P. H. A.

SOUTH CAROLINA MILK

THE Borden Company has decided upon establishing a large plant to manufacture powdered milk somewhere in South Carolina. This decision is due to a recent conference between Dr. L. J. Auerbacher of the Borden Milk Co. and Dr. William Weston, Director of the South Carolina Natural Resources Commission.

Dairy studies have proved that South Carolina milk contains a high content of iodine and other properties especially beneficial to children.

WALTER BURNS SAUNDERS MEMORIAL MEDAL

THE third award of the Walter Burns Saunders Memorial Medal for outstanding service to nursing will be made in April, 1932, at San Antonio, Tex., during the convention of the three national nursing organizations. The first award was made posthumously at the biennial convention of 1930, to S. Lillian Clayton, former President of the American Nurses' Association, and the second presentation of the medal was made to Mary Sewell Gardner of Providence, R. I., in May, 1931.

CANADA-UNITED STATES RECREATION CONGRESS

THE Canada-United States Recreation Congress will be held in Toronto, October 5 to 9. This is the

eighteenth such gathering sponsored by the National Recreation Association, but the first in Canada where progress in public recreation has been rapid during the past 10 years.

The Earl of Bessborough, Governor General of Canada, has agreed to serve as honorary patron of the conference, and Richard B. Bennett, Prime Minister of the Dominion, is the honorary president.

THE HOME AND THE CHILD

AN ANNOUNCEMENT is made of the publication of *The Home and the Child*, covering the findings of the Subcommittee on Housing and Home Management of the White House Conference on Child Health and Protection. This volume of 165 pages presents the recommendations of the subcommittee in regard to housing, furnishings and equipment, the management of home activities, the management of income, and clothing. It is published by The Century Co. The list price is \$2.00.

ASSUMPTION PARISH CHILD HEALTH CAMPAIGN

A PARISH-wide meeting was held in Napoleonville, La., for the awakening of interest in ways and means of correcting defects found in school children during the past school year. Arrangements were made for a bus-load of children to be transported to Charity Hospital on each of four dates during the summer for tonsillectomies.

GORGAS ESSAY CONTEST

HELEN DALE, a recent graduate from Point Loma Junior-Senior High School in San Diego, Calif., was awarded the Charles R. Walgreen Prize of \$500 for the winning essay in the Third Annual Gorgas Memorial Essay Contest. The subject this year was "Keeping Fit: The Gorgas Program of Personal Health."

AMERICAN RED CROSS ROLL CALL

THE Fiftieth Anniversary Roll Call of the American Red Cross, to enroll members for 1932, will be held from Armistice Day to Thanksgiving, November 11 to 26, 1931.

CHINA'S PUBLIC HEALTH

PLANS for the development of public health education in China, in which W. W. Peter, M.D., Dr.P.H., Fellow A. P. H. A., is serving temporarily as technical expert, are published in the June issue of *The Cleanliness Journal*.

Dr. Peter, who was at one time associate secretary of the American Public Health Association and is now director of Health Service of Cleanliness Institute, is on 8 months' leave of absence at the request of the Chinese Government. Previously he spent 15 years in China and was director of the China Council on Health Education.

MOBILE HEALTH UNIT

A MOBILE health unit is the latest in health activities in West Virginia. The unit consists of a trained public health officer and a public health nurse. Under the present plan this unit will visit those counties in the state where there is no established health work, with a view to organizing committees and putting on a demonstration which will not only show the citizens the value of health work but will also give the rural children the same health protection which is being given others in the state. Dr. R. H. MacLeod has been secured as head of this unit.

NATIONAL SOCIETY FOR PREVENTION OF
BLINDNESS APPOINTS NEW
DIRECTORS

THE National Society for the Prevention of Blindness has announced three new appointments to the Board of Directors—Dr. John M. Wheeler, Professor of Ophthalmology in the Medical

School of Columbia University, Mary Antoinette Cannon, of the New York School of Social Work, and Dr. A. B. Meredith, Professor of Education at New York University.

INTELLIGENCE OF DRUG ADDICTS

DRUG addict prisoners who have committed offenses against the United States, and who are no longer taking drugs, show, according to preliminary studies of the U. S. Public Health Service, a greater proportion of above average intelligence than is observed among non-addict prisoners.

Among the drug addicts studied, 30 in every 100 were above average in intelligence, whereas 18 in every 100 prisoners not addicted to the use of drugs were above the average in intelligence. On the other hand, 17 in every 100 drug addict prisoners were considered to be normal but of dull intelligence, whereas 1 in every 10 addict prisoners was mentally defective and 1 in every 6 among the non-addict prisoners was mentally defective.

MALNUTRITION AND ECONOMIC
DEPRESSION

TO students of public health the increase in disease as the result of unfavorable economic conditions has long been known. In this city we have been watching for evidence of the effect of the current economic depression, and we have already observed an unfavorable influence on the incidence of tuberculosis.

A survey of the health of school children recently completed affords another example of the influence of the economic depression. The survey included 2,835 school children examined for evidences of malnutrition in 15 public schools in the Borough of Manhattan. The findings were compared with the results obtained in the examination of 1,881 children in these same schools in 1929. In 1929 the examination of 1,881 children

showed 19 per cent to be suffering from malnutrition; in 1930 the examination of 2,835 children in the same schools showed 25 per cent to be classed as cases of malnutrition.—*Weekly Bull.*, Dept. of Health, City of New York, XX, 16 (Apr. 25), 1931.

TRICHINOSIS

TWO farmers in the western part of the State of New York bought a 320-pound hog and had it butchered. The day after they made it into sausages and they and members of their families sampled the raw sausages and again when partly cooked on that day. These farmers also sold some of the sausages to a number of nearby families during the next 10 days to 2 weeks.

An outbreak of 24 cases of trichinosis followed. Besides the two farmers who had purchased the hog, members of their own, as well as of 8 other families, contracted the disease.

The symptoms were those of gastrointestinal disturbance, together with rise in temperature, edema of eyelids, and deep-seated muscular pain. A high eosinophil count was also reported. *Trichinae* were found on biopsy and also on microscopical examination of part of the sausage and of the head of the hog.

Thorough cooking of all pork and pork products is the only sure safeguard against contracting trichinosis.—*Health News*, May 11, 1931, New York State Dept. of Health, Albany, N. Y.

DENTISTRY IN AMERICA

WITH 67,000 dentists, 1 to every 1,700 persons, America leads the world in dentistry and dental training, according to the Office of Education, U. S. Department of the Interior, in spite of the fact that it has been estimated that only one-fourth of the American people receive dental service.

Thirty-eight institutions in the United States offer professional training in den-

tistry, 31 of which are rated Class A, 6 are rated Class B, and 1 is unclassified. The first dental school in the world was Baltimore College of Dental Surgery, which gave instruction leading to the D.D.S. degree and graduated 2 students in 1841.

PERSONALS

DR. SHIBASABURO KITAZATO, noted bacteriologist of Tokio, Japan, died June 13. He was a member of the American Society of Tropical Medicine, of the International Society for Scientific Research, and was honorary president of the Japan Medical Society.

MRS. FRANCES RICHARDSON BIGGS, widow of the late Dr. Hermann M. Biggs, former New York State Health Commissioner, died suddenly of heart disease May 30.

Mrs. Biggs shared actively in her husband's concern for the protection of the public health. She was president of the National Federation of Day Nurseries and vice-president of the Stony Wold Tuberculosis Sanatorium at Lake Kushaqua. She was an Associate Member of the American Public Health Association.

E. G. EGGERT, formerly of the Texas State Department of Health in Austin, is now Assistant Engineer, Georgia State Health Department, Albany, Ga.

DR. W. T. HENSHAW has been reappointed State Health Commissioner of West Virginia, as announced by Governor William G. Conley.

NEW HEALTH commissioners in Ohio include a change in a general health district and an appointment in a new city under the 1930 census. Dr. Henry R. O'Brien, Lorain County, at Oberlin, succeeds Dr. C. D. Barrett; and James Hobson is the Health Commissioner at Mingo Junction.

DR. W. F. DRAPER has recently been appointed by Governor Pollard of Virginia as the new State Health Commissioner of Virginia. Dr. Draper succeeds the late Dr. Ennion G. Williams, who for over 25 years served as the Health Commissioner of the state and died June 6.

DR. HAIM YASSKY, who has been serving as Acting Director of the Hadasah Medical Organization in Palestine, has recently been appointed Director.

DR. EUGENE LYMAN FISK, medical director of the Life Extension Institute of New York and a pioneer in public health promotion work, died unexpectedly in Dresden, Germany.

Dr. Fisk had been medical director of the Life Extension Institute since its organization in 1913 as a result of a movement headed by former President William H. Taft. Professor Irving Fisher, of Yale, and Harold A. Ley. He has been a member of the A. P. H. A. since 1915 and became a Fellow in 1922.

WILLIAM S. KEISTER, M.D., of the Maryland State Health Department, died July 3.

Since his graduation from Johns Hopkins Medical School in 1914 Dr. Keister had served with distinction in the U. S. Public Health Service and in various state health agencies. He has been a member of the A. P. H. A. since 1913.

CALVERT L. ESTILL has become director of the West Virginia Department of Public Welfare, which was created by the last legislature.

JOHN A. THABES, M.D., of Brainerd, Minn., has been elected President of the Minnesota State Board of Health.

DR. HARRY A. REESE, Health Officer of Yuma, Ariz., and member American Public Health Association, was appointed President of the Arizona State Medical Association at its annual meeting, May 7, 1931.

LEO STEIN, formerly vice-president, has been elected president of the New York League for the Hard of Hearing, Inc.

CONFERENCES

July 27–August 2, The World Federation of Education Associations, Denver, Colo.

August 3–8, International Congress of Industrial Accidents, Geneva, Switzerland.

August 3–8, International Dental Congress, Paris, France.

August 31–September 4, International Neurological Congress, Berne, Switzerland.

September 7–8, International Association of Preventive Medicine, The Hague, Holland.

September 7–10, International Congress for Studies Regarding Population, Rome, Italy.

September 14–17, Sixtieth Annual Meeting, American Public Health Association, Montreal, Canada.

September 20–26, Argentina First National Congress on Social Service for Children, Buenos Aires, Argentina.

September 23–30, Centenary Meeting of the British Association for the Advancement of Science, London, England.

October 5–9, Canada-United States Recreation Congress, Toronto, Canada.

October 12–16, Nineteenth Annual Safety Congress and Exposition, Chicago, Ill.

October 19–23, American Dental Association, Seventy-Third Session, Memphis, Tenn.

November 9–14, the Ninth Texas Sanitarians' Short School, Houston, Tex.

July, 1932, The Second International Conference of Social Work, Frankfurt, Germany.

The Certification of Laboratories in California*

WILFRED H. KELLOGG, M. D.

Bureau of Laboratories, University of California, Berkeley, Calif.

THE fact that there are many untrained, inexperienced and incompetent technicians daily performing laboratory tests, the outcome of which may be a matter of life or death for some patient, is not generally appreciated. The work of such technicians is sentencing some patients to unnecessary anti-syphilitic treatment, allowing others who should be treated to go without treatment, or helping other patients to an unnecessary abdominal operation through a false blood count, and generally confusing the diagnosis for the doctor who seeks light on obscure conditions.

In the public health laboratory, such technicians release contagious cases and carriers, or place in quarantine persons who are not a menace and should not be detained. Any way one looks at it, it is a serious matter that such important service should have no safeguards whatever.

If a blacksmith's apprentice wants to treat the sick for pay, he must take a medical course lasting years; even if he wants to be a chiropractor, he must take some sort of course and procure some sort of license, but if he wants to make laboratory diagnoses for physicians and their patients—literally engage in one phase of the practice of medicine—all he need do in most places is buy some equipment, or get a job and go to work.

The need for protection of the people, their physicians, and the health departments against a low standard of service in this important field, is evident to every competent laboratory man, and to every phy-

* Read at the Meeting of the Western Branch, American Public Health Association, Seattle, Wash., May 29, 1931.

sician who is himself sufficiently in touch with laboratory methods to recognize ignorance and charlatanism, when it appears in the guise of diagnostic laboratory service; for there are charlatans as well as incompetents in diagnostic laboratories, as there are in the general field of medicine. Physicians curiously enough do not seem to appreciate that this problem exists. They apparently do not apply to their laboratory technicians the same reasoning regarding the necessity of adequate education and experience that they apply to themselves. It is doubtless to be explained by the lack of thought and attention that is given this specialty of medicine by the profession in general. Whatever the explanation, it is a fact that less concern is shown by the average individual physician in routing his specimens to a laboratory, and by the average group or hospital in employing a laboratory worker, than to almost any other type of service of which they make use.

The influences that determine the physician's choice of a laboratory are without doubt generally the same that influence patients in selecting their physicians. For some patients, the doctor's sign on the door is sufficient, and for some doctors the statement of the applicant for a job that he or she is a bacteriologist or that he or she is fresh from the laboratory of some hospital, is sufficient. True, the former job may have been that of dishwasher, but this unfortunately may not be gone into. Others may be more cautious; they may require the recommendation of someone else no more qualified than they, to decide on the technical qualifications of the seeker after employment or referred business. Some will pursue the course adopted by a very few patients in choosing their physicians, and in the absence of any official certifying agency, seek the advice of someone who has special knowledge in that particular line.

Such things as personal appearance, convincing manner, a "line of patter" suggesting technical knowledge, a pleasing personality, are very effective in "selling" the laboratory worker to the physician; while the fact that a technician without previous training cannot become competent by working in a laboratory for a period of only 2, 4, or 6 months, is usually lost sight of.

An education in the basic sciences of chemistry, bacteriology, biochemistry and pathology is almost as necessary as for the practice of medicine, and even after the best of college courses, experience under competent supervision is necessary. The average physician, health officer, or hospital executive is not prepared to pass on the qualifications of a technician, and therefore must have some method of distinguishing the competent from the incompetent.

When such facts become common knowledge among physicians,

and others having the selection of directors of laboratories and technicians, both for public health and for clinical work, there will no longer be a problem. Until that time, it seems incumbent on those having a knowledge of the facts, and who are at the same time in a position to improve conditions, even in a limited way, to take such action as their judgment dictates.

My interest in the matter of dependable laboratory service was first aroused as a result of my observations while acting as State Epidemiologist in conjunction with my work as director of the State Laboratory. Later, while executive officer of the department, I tried to get a bill passed by the legislature to establish a licensing system for all diagnostic laboratories, both public health and clinical. This plan was distrusted by the medical profession, at least that part of it which took any interest at all in what was going on in the legislature, and it met the active opposition of certain commercial laboratories. I saw it was no use and dropped the matter entirely, but it seemed as though something should be done. Waiting for improvement through a growing appreciation of the situation on the part of the medical profession, would be like waiting for the millennium. If the doctors had waited for the people to learn that they should, in their own interest, have state licensure of physicians, there would as yet be no restriction on the practice of medicine and surgery. Likewise, waiting for the laboratories themselves to clean their own houses while perhaps promising more, still, seemed too far in the future. Such a waiting policy had no appeal.

Finally, in 1923, we decided to try a voluntary system of approval of laboratories, intending at first to limit our field to public health. Sanction of the State Board of Health was secured, and the work was started, using printed forms patterned after those of New York State, in their work of subsidizing laboratories for public health work. This plan met with a very favorable reception from the local public health laboratories, and when a few clinical laboratories asked for certification, they were included.

In the operation of this plan, an application for certification is followed by a personal visit to the laboratory. The applications are made in writing, on a special form provided by the department. Questions are answered regarding educational qualifications and experience of the director, the number of employees, the physical equipment of the laboratory, types of work performed, etc. The applicant also agrees to keep careful records of work done, including the preservation of certain stained slides, for a definite period, and to submit to inspection as required.

It has not been considered necessary or advisable to require particular methods of examination, but if the method in use is not considered a safe or effective one, approval is withheld unless a satisfactory method is adopted.

Under the regulations of the board, the director of a laboratory, if not the owner, must have full authority to control the policy of the laboratory so far as technical matters are concerned. The records that are required to be kept are those pertaining to the examination of specimens, such as results, name of patient and of doctor who submitted the specimen, etc. The recording system must also be such that any particular specimen can be readily found and connected up with the case.

Financial matters, fees for examination, etc., are not inquired into. Changes affecting the directorship, removal of laboratory to new location, or radical changes in technic, must be reported to the director of the State Laboratory. A change in directors cancels the certificate of approval.

Such was the system at the beginning, with no examinations of either director or technicians, no requirement of the medical degree for directors of clinical laboratories, no inquiry into the quality of their work in the clinical field. It soon developed that certain local public health laboratories could not be approved, although the local health officer desired that his laboratory be so recognized. In one particularly flagrant case, the health officer was unable for political reasons to make the changes recommended. It was clear that some form of compulsion was necessary. Another bill was drafted, and with the previous experience fresh in mind it was made very brief, very general, and limited in application to the public health laboratories. Following is the wording of the law which was passed in April, 1927:

MUNICIPAL AND COUNTY LABORATORIES

(Act approved April 29, 1927)

1. Any incorporated city, town, county, city and county or chartered city may, for the purpose of protecting the community against infectious disease, establish a bacteriological and chemical laboratory for the examination of specimens from suspected cases of disease and for the examination of milk, waters and food products.
2. The cost of establishment and maintenance of such laboratories shall be a legal expenditure from any incorporated city, town, county, city and county or chartered city funds that may be provided for disbursement under the direction of the health officer for the protection of public health.
3. All municipal and county laboratories established for the purposes herein set forth shall be subject to the approval of the state board of health.

The Board then passed the following set of resolutions for the enforcement of the act:

REGULATIONS FOR THE CONDUCT OF LABORATORIES

WHEREAS, Chapter 282, Statutes of 1927, requires the State Board of Public Health to supervise the bacteriological laboratories maintained by cities, cities and counties, counties and towns, the following requirements are hereby established for the operation of such laboratories:

1. The certificates of approval heretofore issued to laboratories on a voluntary basis shall be required to be in the possession of all city, city and county, county and town public health laboratories and no such laboratory shall continue to operate more than 5 days following receipt of notice of cancellation of any existing certificate, or of refusal of the board to issue a certificate in the first instance, except on temporary extension granted for cause by the Director of Public Health.

2. All skilled workers in municipal or county public health laboratories including bacteriologists, serologists, technicians or laboratorians shall possess, as the condition for such employment, certificates of proficiency issued by the State Board of Public Health.

3. Examinations either written or oral or both for the certificate of proficiency shall be held from time to time in such geographic centers of the state as will best suit the convenience of the majority of the applicants or as may be designated by the Director of Public Health.

4. Examinations for certificates of proficiency shall be under the supervision of the Chief of the Bacteriological Laboratory, State Department of Health.

5. Two grades of certificates shall be issued, one for bacteriologists and one for serologists. Workers possessing one certificate only shall not be permitted to engage in the activities covered by the other certificate, excepting under the immediate supervision of some one possessing the requisite certificate.

6. Health Officers of municipalities or counties possessing no laboratory, but who desire local laboratory service, may designate a local, private laboratory as the official public health laboratory of their territory, but any such designation shall be subject to the approval of the State Board of Public Health, and all skilled workers in such laboratories entering such contract shall hold the appropriate certificate or certificates of the State Board of Public Health.

Adopted by the California Board of Public Health in regular session on the 12th day of November, 1927.

This law with the regulations has accomplished its purpose, for although it has happened that a city has been reluctant to follow the demand of the board that an incompetent technician be displaced, the matter has never been carried to the courts, from which I judge that legal advice has been to the effect that the board has full power under the act.

As a preliminary to the inauguration of the certification of technicians, I visited all the approved public health laboratories in January, 1928, and gave an oral examination to the various technicians, and certificates of proficiency of either junior or senior grade were

issued. Thereafter, all examinations have been written, and have been held at advertised places and times. The system of calculating credits for the certificate is designed to encourage the taking of college courses in preparation for a laboratory career, but at the same time to take care of the practically trained person if he or she is really competent.

A recent graduate, even after the best of courses, still lacks something that can only be obtained by a season of practical experience which may however be rather short if taken in a laboratory doing a great deal of work, and in association with other good technicians. Therefore, the credit given for a college course is hardly sufficient, even with a good examination paper, to secure the senior grade certificate, which entitles the holder to engage in work unsupervised. Credit for practical experience, on the other hand, is not so great as to make it easy for a worker with only a couple of years' experience to get the senior certificate. One-half of the final credits are represented by the paper, one-third by experience, and one-sixth by relative capacity, so-called. The latter is arrived at in a personal interview.

On a basis of 100, 1 year's experience gives a credit of 40, 2 years' of 50, 3 years' of 60, 4 years' of 70, 5 years' 80, 6 years' 90 and 7 years' 100. The experience must be in a laboratory providing the proper kind and quality of experience for the certificate in view. Credit for college degrees is as follows: A.B. (or B.S.), with a major in a subject directly related to the field covered by the certificate, 3 years.

If, in addition to the academic course required by the major, a special advanced or postgraduate course approved for this purpose is taken, a credit of 5 years is given. If, in addition to this last, a period of 3 months is spent as a voluntary assistant in a laboratory particularly designated for that purpose, a total of 7 years or 100 per cent is given.

The basis for approval of clinical laboratories was at first the same as for public health laboratories. Later, it was required that the director of a clinical laboratory should have the M.D. degree, and it was further decided that the endorsement by the Board of Health of a clinical laboratory should be supported by actual knowledge of the qualifications of the technicians employed therein, since their supervision in some laboratories is not very close. The certificate of proficiency in biochemistry, including general clinical laboratory work was therefore established and also a certificate in parasitology.

Until recently, certificates have not been required of workers in laboratories that are under the direction of a doctor of medicine who is specializing in this field and devoting his whole time to the work.

After January 1, 1933,* however, all approved laboratories whether clinical or public health must display at least one senior certificate for each of the divisions of laboratory work that may be undertaken, and all persons on the staff, except medical directors and apprentices, must hold either a senior or junior certificate for the particular kind of work they are required to do.

SUMMARY

Since 1923 the California State Board of Health has issued to certain laboratories, both clinical and public health, certificates of approval.

In 1927, the possession of such certificates of approval was made compulsory for the official public health laboratories of the state. Among other requirements, an approved laboratory must employ certified technicians.

Certificates of proficiency are issued to individual workers after written examination, and special credit is given for college degrees and practical experience.

Certificates of proficiency are issued in 2 grades, junior and senior, and of 4 different kinds, to take care of the varying scope of work in different laboratories. The 4 certificates are in bacteriology, serology, parasitology and biochemistry, the latter covering all activities not included under the other 3.

* Resolution of the Board of Health, Apr. 11, 1931.

Medical Service in Public Schools in Turkey

A RECENT ministerial decree in Turkey provides, evidently for the first time in that country, medical service in secondary schools, which are attended by children mostly between 13 and 16 years old. Each pupil must be examined at the beginning of the school year and at least once more during the year, and a detailed report about each must be sent to the school principal. The examining physician is expected to decide whether the pupil is able to follow the studies without physical or mental harm. A health record is to be kept for every pupil. Pupils with certain defects are to be put on special registers and to be kept under observation. The school physician is also required to watch the sanitary conditions in and around the school building and to give to the school children frequent lectures on hygiene.—*La Législation Turque*, Editions Rizzo, Stamboul, 1931, N. I.

Important Factors in Directing the Health of the College Woman

ESTHER WAGNER STEARN AND GRACE RAND MITCHELL

Department of Hygiene and Physical Education, Christian College, Columbia, Mo.

IN an article appearing in this *Journal*,¹ Dr. R. W. Bradshaw discusses the problem of student health as a new science. He stresses the unique opportunity in the student health service for research as offered in the field of health appraisal, disease prevention, nutrition, mental hygiene, and epidemiology. Already statistics exist and it may appear not unwise to probe somewhat deeper into the active life of the student, to determine if so-called natural unfitness occasioned by disturbances, considered minor and unalarming, are not of greater importance than is generally recognized.

The physical examination of students entering college serves to eliminate the physically unfit as well as to detect defects in those who matriculate, with the aim of providing remedial as well as protective measures. The records of this school show that it serves this purpose. However the absence of ill health does not imply that the condition of perfect health prevails. Symptoms which call for or even permit a physical consciousness on the part of an individual are often considered by students as legitimate excuses for the avoidance of exertion. These same symptoms however are regarded as natural in the developmental cycle and therefore are relegated to the inevitable and unalterable, no matter how distressing and devitalizing. Such notions are paradoxical.

A recent survey shows that specific factors incapacitate the woman student. The most common symptom of organic disturbance is headache. Studies of 225 girls, whose ages vary from 16 to 21 years, show that 78 per cent complain of headaches. The frequency varies from three times a week to twice a year. Eighteen per cent of these have headaches not less often than once a week. In 71 cases the doctors have named as many as 14 different causes. Eyestrain, nervousness, worry and stomach trouble are listed as main causes. In 41 cases, eyestrain has been diagnosed as the cause. In the other cases no attempt at diagnosis has been made. The cause is not eliminated and the girls supply their own remedies. Fifty-one per cent of these girls use aspirin, others use pills, laxatives, soda water and the like. Some

rest and discontinue study. The survey shows that a great deal of time is lost through headaches, despite the fact that regular habits of work, recreation and rest are enforced.

Another symptom which has been intensively studied by medical men is growing pains. It is recognized as a form of rheumatism caused by some focal infection, and statistics show that heart trouble is more commonly found in those whose history shows rheumatism. Dr. L. F. Barker and Dr. Norman B. Cole² state that "from 80 to 95 per cent of heart trouble in young people is due to rheumatic fever." They further state that the fleeting pains known commonly as growing pains were not until recently looked upon as manifestations of rheumatic infections. They stress the importance of examination, at regular intervals, of teeth, tonsils (which even when removed may grow again), nose, ears and the whole respiratory tract, to insure that they have not become focuses of infections.

The survey shows that 56 per cent of the 225 girls have their teeth examined twice a year, and 25 per cent once a year. The others do not do so at all regularly. Six per cent claim they never have had their teeth examined and cleaned by a dentist.

One hundred thirty-three girls had growing pains at some time. Of these 13 per cent still suffer from them. Our study further shows that 47 per cent of the 225 girls have had their tonsils removed but that in 6 per cent of those who had growing pains there is at present a recurrence of the pains. Of the 58 per cent of girls whose tonsils have not been removed 11 per cent of those who reported growing pains still have them. This shows that a smaller number of girls in the latter group, and a far greater number in the former have lost this symptom of focal infection.

Another form of organic disturbance lies in abnormal menstruation, where this period is of excessive duration, the pain unduly great, and the loss of vitality excessive. Doctors seem to agree that a normal woman should not be incapacitated for work during the menstrual period. The survey shows that this condition of normality is not universally true. Fourteen per cent of the girls remain away from classes regularly during some part of the period, while 34 per cent take drugs to deaden the pain. The majority have periods extending beyond the 5-day limit, and 63 per cent complain of pain. Twenty-four per cent do not have a definite menstrual cycle. About 21 per cent go to the infirmary for part of the time. We may compare this condition with a statement by Dr. Clelia Mosher³: "The best developed women who have come under my observation have a period of not more than 2 or 3 days, free from pain, and in many cases are at their maximum effi-

ciency every day in the month." Dysmenorrhea is thought to be caused by bad posture, poor muscular development, constipation, and chest instead of abdominal breathing. Dr. Mosher stresses the importance of exercise for the normal woman and that for her there should be no suffering and no incapacitating effect of this normal physiologic process.

Colds cause a greater loss of time and efficiency than any other sickness. Little is known about the prevention of colds other than that proper care of the body—that is, proper food, sleep, bathing, avoidance of prolonged exposure, absence of obstructions in nose and throat—increases the body resistance to it, and that care in preventing the spread of nose and throat secretions will lower the incidence. In a school where rules provide for the hygienic modes of living, and sanitary conditions prevent the spread of infectious material it may seem strange that as high as 34 per cent suffer from frequent colds and another 18 per cent occasionally do so.

The question arises as to the possible relation of dietary habits to this frequency of colds. Seventy-two per cent of girls are hungry between meals and eat more or less regularly between meal times. The majority gain in weight. Two measures for prevention of colds that are usually mentioned are avoidance of overeating, especially sweets, and constipation. This study bears out such relation by showing that a higher percentage of those who do not have colds have regular habits of evacuation; that is, of those who have occasional colds 20 per cent, and of those who have frequent colds 35 per cent suffer from constipation. Of those who do not suffer from colds only 16 per cent are constipated. Depression, headache and lassitude accompany attacks of constipation and thereby add to the menace from this factor.

It may be significant to compare the data relative to a group of 25 students with superior ability to 25 with inferior ability. Of the first group 32 per cent diet to reduce weight and of these 75 per cent are subject to colds. Of the second group 36 per cent diet to reduce weight and of these all are subject to colds. Of the entire 225 girls, 36 per cent diet to reduce weight.

It has been known that injudicious dieting, not regulated by a knowledge of the essential food elements nor the advice of a physician not only increases constipation but that the subsequent lowered resistance increases the susceptibility to tuberculosis.

The above is interesting from the standpoint that the school has an enviable record of good health when good health is interpreted as the absence of contagious disease. Rules of the school and its equipment and staff provide for regular and nourishing meals, sleep, proper

ventilation, supervised recreation, instruction in corrective gymnastics, and hygienic modes of living. At the same time the symptoms of physical discomfort as testified to by students themselves, by absences from classes while remaining in the infirmary, and by poor response at times on the part of students of good mentality call for further inquiry. Reference to the factors employed by students on their own initiative shows several interesting facts.

Thirty-two per cent use cathartics advised by physicians. We quote from Drs. Smiley and Gould: "To begin the habitual use of laxatives and cathartics at college age is extremely unwise, because the great majority of cases of constipation occurring at that age are preventable or curable by means much more physiological." Fourteen per cent take a cathartic fairly regularly.

Sixty-eight girls take some kind of medicine for coughs, liver, colds, malaria, stomach trouble, heart, nerves, sinus trouble, dysmenorrhea and vitality. None take reducing pills but 36 per cent diet to reduce weight. One hundred and forty-nine girls take aspirin. Of these, 116 take it to kill headaches, 41 for menstruation, 20 for colds, 1 for hay fever, 13 to produce sleep, 3 for nerves and 2 for heart.

This survey indicates:

1. Only a few, i.e., 18 out of 225 girls, take tonics. Contrasting this condition with the general use of tonics 20 years ago we are forced to believe in the great physical improvement of the college woman. This improvement is due in part to the increased activity and the non-constrictive clothing of the modern woman. Dr. Mosher⁵ says: "An extraordinarily close correlation was found between the fashion of dress and the menstrual condition of women. As the skirt grew shorter, narrower, and lighter in weight, and the waist grew larger, the functional health of women improved."

2. Since a large number of girls still suffer from, and are incapacitated by, headaches, growing pains, dysmenorrhea, and colds, there remains the necessity for earlier training in proper health habits than is at present provided for most girls, especially since these ailments are thought to be corrected by such means.

3. Since more time is spent in the infirmary by students with low I.Q. than by others, an intensive study of such students should be made in terms of their health habits.

4. A closer coöperation between educators and physicians as well as hygienists is advised in the attempt at explaining and correcting the factors which make for inferior mental response. In connection with the above findings resulting from the survey it was thought worth while to compare certain of the data furnished by students of high I.Q. (as measured by a psychological examination for high school graduates and college freshmen), with those of low I.Q. To obtain as great differentiation as possible, out of the 225 cases for which data were at hand, the 25 individuals with the highest score (276-180) were compared with the same number with the lowest score.

It was found that 48 per cent of the high score group never go to the infirmary while only 28 per cent of the low score group are this fortunate. Twenty-four per cent of the former group are subject to colds as compared to the 40 per cent of the latter. Forty-four per cent of the former suffer from headaches, while 64 per cent of the latter do so. Of the 36 per cent of the low score who diet to reduce, all are subject to colds and do not have daily defecation, while of the 32 per cent of the high I.Q. who diet only $\frac{3}{4}$ of this number have colds and only $\frac{5}{8}$ fail of daily defecation. However, 90 per cent of those in the low score are hungry at other than meal times, a condition reported by only 65 per cent of those in the high group. Three times as many individuals of the low score use cathartics as do those of the high score.

In all phases of active interest the individuals with high scores show pronouncedly greater activity. More time is spent in study, in extra-curricular activity, in physical training, in leadership work by those in the high scores.

From this study which has taken into account habits of bodily care, modes of relaxation as well as the simplest factors in maintaining physical and mental health, there arises the problem of correlation of cause and effect in those students who enter college mentally inferior and handicapped by low vitality. Is this sluggish response to be related to maladjustment in early life? to focal infections? to the presence of intestinal parasites such as ameba? or to hookworm which produces the symptoms of anemia, malnutrition and mental retardation?

In conclusion, the authors wish to point out that the accepted standards of physical examination of the college student by medical men must be supplemented by closer examination of physiological processes and we must not be contented with the detection of defects in the mere mechanisms of the body.

Public Health Organization*

KENDALL EMERSON, M. D.

*Acting Executive Secretary, American Public Health Association,
New York, N. Y.*

I HAVE travelled across the continent for the express purpose of bringing to the Western Branch the greetings of the American Public Health Association on the occasion of this, your second Annual Meeting. It is a long journey. Each time I take it I am reminded of the old story of the Englishman who spent several months seeing the varied sights of our great country. When about to sail for home he remarked that it did not seem at all surprising to him that Columbus had discovered America. The wonder would have been if he had missed it.

And each time I come I appreciate more fully than before that there is something which you people have out here which we miss in the East. I am not going to try to define it. Call it the pioneer spirit if you will. The fact remains that there is an enthusiasm, a spontaneity, a self-reliance which we of the more formal and older parts of the country recognize and envy in you, your loyalties, your energy, the keenness with which you go about your enterprises, such as this extraordinarily interesting and highly scientific meeting you are putting on here in Seattle at the moment. We need your contagious buoyancy. Yet we are not willing to admit that there may not be things we have back East which you need too. After all, this is one country, though a big one; its needs are more or less common needs; certainly its public health program is not a sectional matter but one which interests all parts of the land equally, and draws us all very close together in a common bond.

So as a representative of the parent organization I bring to you of the Western Branch most cordial greetings, heartiest congratulations on this splendid meeting, best wishes for your continued growth in strength and for your increasing influence for good on the health and welfare of the states of the Pacific Coast and the Rocky Mountain region. Back there in New York you may always count on our lively sympathy with your ideals and aspirations, and, what is more impor-

* Abstract of address at a dinner session at the Second Annual Meeting of the Western Branch, American Public Health Association, at Seattle, Wash., May 29, 1931.

tant, our constant readiness to be of every possible aid to you in this great common task upon which we are all engaged.

Tonight I propose to speak to you very briefly on the somewhat broad topic of public health organization. I shall confine myself to a limited phase of that topic, the relation of the official to the volunteer health organization. This is a peculiarly American problem, an outgrowth of our democracy, and would have little pertinence as a subject for discussion in a more centralized form of government.

Speaking broadly, there are just two forms of government, the despotic and the democratic. Of course they shade into each other but as examples of the rather extreme types we may take on the one hand the absolute rule of the small Communist party in Russia or the single despot, Mussolini, who now controls Italy; and on the other these United States of ours consisting of 48 empires loosely held together by a federal government whose impossible duty it is to interpret and satisfy the separate desires of 120 million rugged individualists. If a dictator decrees vaccination, even the conscientious objector bares his arm. But the free born American citizen, if he chooses, may bear the proud scars of smallpox throughout his independent life, a monument to his ignorance and blind self-conceit.

In a democracy, successful public health service must, of course, have legal sanction, but far more than on that it must depend on an educated public with which to work. Now at best public health officials and workers are limited in number. Their administrative and technical duties leave little leisure for the slow and painful process of educating public opinion. You are fully aware of the millions spent each 4 years in an attempt to make the voters of this country think republican or think democratic. There are no such resources at the command of the public health service, though it would be far more profitable if this money spent politically could be turned into the productive channels of health. In a democracy, then, the problem of the public health requires a different mode of handling from that possible to absolutism.

As an illustration you will perhaps permit me to speak of the National Tuberculosis Association as the volunteer health organization with which I am most familiar. It was started 27 years ago by a group of keen visioned public health physicians who recognized that the preventive medical knowledge even of that day was not beginning to be used because the people had not been taught to want it. Nor was the public health service equipped with means to do the teaching. A great popular educational program was needed and this the association undertook. Its first step was to make the organization one of

both physicians and laymen, a wise provision since the latter are sometimes more acceptable as teachers than are physicians of whose motives the public is inclined at times to be suspicious.

The scheme worked even better than its founders had hoped, and other similar organizations were developed. Now it must be remembered that in the beginning the idea originated from public health men and as an aid to the more rapid application of preventive medical principles. Like many a good sword it had two edges. In some localities the influence of the volunteer organization outran the resources of the official health department. Rather feeling its oats the volunteer association sometimes took a community leadership which should have been the prerogative of the health official. Not infrequently it was unreasonably critical rather than constructively helpful. The health officer quite properly resented this, and certain echoes of ancient and most unfortunate clashes are still audible today.

But speaking for one volunteer association I can assure you that those days are over. The value and success of a state or local tuberculosis association is measured at the national office in terms of how far it has integrated its program with that of the official department with which it is in touch. Just in proportion as it is recognized as an arm of the official service just so far it is approved. The health officer is sought as an active member of its Board of Directors. No enterprise is undertaken without his full knowledge and coöperation. His requests are commands to the full extent permitted by the limitations of the organization's resources. When the official department is equipped to carry on without our aid we transfer our duties and seek new ones. If the time comes when the resources of the official health service are adequate we will go out of business. The time is far distant however, as many a harried health officer will testify.

Before concluding I want to take up one other matter. Due to the fact that I have assumed the Acting Secretaryship of the A. P. H. A. while still Managing Director of the N. T. A. whisperings have arisen that an amalgamation might be foreshadowed between the two organizations. Nothing could be farther from the truth. It is impossible in the nature of things. Oil and water won't mix and in both form and purpose the two associations are strikingly dissimilar. The N. T. A. is primarily an operating organization. True we do some research work and hold an annual scientific meeting on the subject of tuberculosis. But our primary aim is the maintenance of our field operating service as an adjunct to the official health service. In general this is true of the other volunteer health associations.

On the other hand the A. P. H. A. is primarily a scientific society

composed of the professional workers in their chosen field. Its own members are doing the public health field service of the country under federal, state and local auspices. There is no call for the Association to undertake field operations. But there is every need for a central scientific body in this great profession to represent its interests before the public mind, to carry on a vast amount of research, to set and maintain standards of work, and to act as an expert appraiser of work actually being accomplished. Through its publications and its meetings it is the great clearing house for the newest thinking of the best minds in the profession in all its varied branches. Its future strength lies not in amalgamation with outside associations but in a far closer integration of its many complex branches, a broader realization that with its varied specialties it is still one great profession, one body of many parts, but a body that will survive only as a whole.

The American Public Health Association has an honorable history of now sixty years. Abroad it is looked upon as by far the greatest organization of its kind. Its strength lies in the united strength of the public health workers of America. Enrollment as a Fellow is the crowning recognition of professional achievement.

Chicago Claims of Low Tuberculosis Death Rate Challenged by Sydney, Australia

IN the City of Chicago *Bulletin Nos. 10, 11, and 12*, the claim is made:

For the first time in the history of Chicago, this city in 1930 achieved the lowest death rate from tuberculosis of any city in this country or abroad.

Following this is a list of American cities, headed by Chicago with a death rate of 66.61 per 100,000, representing a decrease of 20 per cent since the taking of office by ex-mayor William Hale Thompson.

Sydney, the largest city of Australia, with a population December 31, 1930, of 1,250,560, had a death rate of 51.30 per 100,000 from all forms of tuberculosis, and a death rate from pulmonary tuberculosis of only 46.08.

The general death rate for Sydney in 1930 was 8.71 per 1,000, the infant mortality rate (deaths of infants under 1 year) was 49.9 per 1,000 births. The average death rate for the previous 8 years was 8.94 per 1,000, the lowest record for any city in the world with a population of over half a million.—Letter to the Editor from J. S. Purdy, M.D., Metropolitan Medical Officer of Health, Sydney, April 20, 1931.

A Study of the Diets of Federal Prisoners*

PAUL E. HOWE, PH. D., AND A. H. MACCORMICK

In Charge of Nutrition Investigations, Bureau of Animal Industry, U. S. Department of Agriculture; and Assistant Director, Bureau of Prisons, U. S. Department of Justice, Washington, D. C.

THE feeding of prisoners presents a peculiar problem; it is to supply food to a group of men, restricted in their activities, doing more or less work, with practically no opportunity to satisfy acquired food habits except by not eating. There is limited opportunity to purchase food, especially fruit, in some prisons. The difficulties of prison messing are those related to the psychological aspects of living. They are the problems of feeding men of varied food habits, arising from different standards of living, religious beliefs, and natural or acquired inclinations. With enough food, of the right kind (as public wards, prisoners should receive an adequate diet), the problems are those of sanitation and planning of the meals, preparation of food, and the method of service.

Food is one of the most important factors in a prisoner's life; it is one of the few things which have an element of variety in them. It would seem to be a wise prison policy to permit as great a variability as possible in the choice of foods, the planning of meals and the preparation of food, provided the results are accomplished through the labor of the prisoners on food of healthful quality and without resorting to the use of delicacies. Highly palatable foods like meat, and the food adjuncts, sugar, oleomargarine and jelly, are desirable when they bring about the consumption of staple foods such as bread and potatoes that do not possess flavor to a marked degree.

As a preliminary step in determining the adequacy of the prison diets as they now exist and to have information on which to base a method of rationing, we have obtained and calculated data on the food furnished the main messes at the United States penitentiaries at Atlanta, Fort Leavenworth, Leavenworth, and McNeil Island, and at the reformatory at Chillicothe, O. The quantities of the various

* Read before the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

January	5.33	.355	5,005	162	182	702	.903	1.86	.029
June	4.77	.332	4,796	147	186	634	.966	1.87	.026
July	5.02	.303	4,869	147	187	648	.999	1.78	.036
<i>McNeil Island</i>									
January	5.06	.287	4,171	137	129	613	.868	1.55	.025
June	5.05	.311	4,288	130	145	478	1.093	1.79	.030

foods used were grouped according to the classification of Miss Hawley.¹ Calculations were also made of the caloric value, protein, fat, carbohydrate, calcium, phosphorus, and iron.

Typical data are contained in Tables I to III. In Table I data are presented for a winter and spring month, and in the case of Chillicothe for the four quarters of the calendar year. The results represent the food supplied, exclusive of ordinary waste resulting in preparation but not corrected for edible food not eaten. In well managed prisons the waste of edible food is about 0.1 lb. per man per day, in others it may be as high as 1 lb. per man per day. The figures given for cost of food represent what is usually designated as gross cost, i.e., the actual money spent for food plus the assigned values for products produced on the farm, especially milk, vegetables and pork. In Table II both gross and net cost are given; the net cost is the actual money expended.

Considered from an abstract nutritional point of view the prisoners received, in general, adequate amounts of protein, fat, carbohydrate, calcium, phosphorus, and iron. The figures given represent the average of the prisons. Some men eat less, some more. Men who work on night shifts usually obtain extra food, all of which is included in the figures given. A record of the number of men not eating meals shows that in some prisons as many as 500 men will miss a meal during the day.

Vitamins seem to be present in moderate amounts. In certain cases the calcium content tends to be low, and in most cases the quantity of phosphorus is about twice that of calcium. For certain domestic animals and the rat such a proportion is not particularly desirable. We do not know the best ratio of calcium to phosphorus for

man. In milk calcium and phosphorus are present in approximately equal proportions. Assuming the proportion in milk to represent that desirable for the adult, there would seem to be a need for the addition of calcium to the prison diets to adjust to this ratio. A correction is not to be accomplished with milk, since it adds phosphorus at the same time; the correction appears to be through an increase of vegetables, the addition of calcium as a salt, or the reduction of meat and grains.

Meat plays an important part in the dietary of a prison because of its flavor and general appeal through which it helps to increase the consumption of the bland foods. The grains are a cheap source of energy yielding food. It would seem, therefore, to be advisable to increase the consumption of calcium through the use of vegetables and also the addition of calcium salts to the ration. The increased consumption of vegetables is at times a problem in itself. The men do not always eat them, due partly to dislike and partly to the method of preparation. An increased consumption is to be attained through skilled cooking or through combination with other foods as in stews or meat loaves.

It is evident from a consideration of the data that the food consumption is high in certain prisons; a matter that is being adjusted at present. The condition in the Atlanta prison is an interesting one. For several years daily calculations of protein, fat, carbohydrate, and energy have been made and the daily ration adjusted to a standard. The present cook takes a great deal of interest in the results that are supplied to him by the storekeeper—the originator, we believe, of the plan. The results obtained are satisfactory with regard to the factors considered; there is a need for more vegetables and milk. The warden is developing his dairy herd to obtain more milk, and plans have been made to raise and can or store vegetables. This plan is present in all of the penitentiaries.

It is proposed to produce as many vegetables as possible on the farm of each prison and to can and redistribute material that can be grown at one prison to better advantage than at another. The condition at McNeil Island also appears to be satisfactory. This prison is in the fruit and vegetable country of the Northwest where vegetables and fruits can be grown or obtained cheaply. At the other prisons the cooking is generally good considering the facilities. The problems of adjusting the ration to a more economical basis are those of preparation, service, and possibly waste.

With the data on Leavenworth are included results for July and August, 1929. In August there was a food riot. These months were immediately following a period of enforced stringency in funds which necessitated a reduction of expenditures for food. Unfortunately this reduction was continued into the next fiscal year. There was apparently sufficient food; the difficulty lay as much in the planning of the meals as in any other factor—the meals of one week were just like those of the next. There was a difference in method of service at Leavenworth between January and June and July. A cafeteria service was in effect in the latter months, but it has not had a marked effect on food consumption or wastage. The data in Tables II and III indicate the distribution of the quantities of the various foods in the prisons, based on a 6 months' average. These figures permit a study of the variation in food habits and of cost.

The present method of rationing has been to set an arbitrary figure from year to year for the cost per man per day—based on the expenses of the past year and probable cost of food in the coming year. It is our intention to evolve a basis for rationing on the food required for a reasonably satisfactory mess under prison conditions.

Taken as a whole the prisoners in the federal prisons receive an adequate amount of food; corrections are desirable in relation to cal-

cium and in some cases in the amount of food eaten. The success of a prison mess rests, therefore, first on the steward, with his ability to plan and prepare palatable meals, to estimate the amount of food the men will eat, and to see that it is properly served; and second with the discipline of the prison which assures an even and adequate service and helps to reduce waste.

Turkey Child Welfare Provisions

THE general public health law of Turkey, which became effective November, 1930, and which is apparently the first of its kind in that country, contains a chapter on child health, and authorizes the Ministry of Health and Social Welfare to "take all measures" necessary for the promotion of child hygiene. Some of the measures prescribed in this chapter are:

1. Establishment of child health centers in cities with a population of over 10,000
2. Periodic physical examinations and mental tests of school children
3. Courses in child hygiene for girls in secondary schools
4. Supervision over boarded out children less than 7 years old
5. Protection by the State of children mistreated by their parents or guardians
6. Pecuniary aid to mothers having at least 6 living children

The chapter on industrial hygiene prohibits the employment of children less than 12 years old, night work for persons less than 16 years old, and the employment of expectant mothers on harmful work for 3 months before confinement; employment on ordinary work is prohibited for 3 weeks before and 3 weeks after confinement; persons less than 16 years old may not work more than 8 hours a day.

The law provides for the enactment of a Labor Code which will contain additional measures for the protection of workers.—Office International d'Hygiène Publique, *Bulletin Mensuel*, Paris, Apr., 1931, p. 598.

Rôle of the Pay-Cost Clinic*

HARRIS R. C. WILSON, D. D. S., F. A. P. H. A.

Supervisor of Mouth Hygiene, Board of Education, Cleveland, O.

MOUTH hygiene activities were started in Cleveland, as in most places, purely as a charity. The object was to provide free dental service for poor children. The idea appealed and still appeals to the philanthropic instincts of members of the dental profession.

Charity is most commendable, but it rarely solves a social problem. Giving people a chance to provide for themselves is much more likely to solve the problems of society.

Cleveland was one of the early participants in the movement to provide free dental service for children. It was more than 30 years ago that the idea assumed material form. Large groups of school children were examined and 97 per cent were found to have diseased teeth. Then came a wave of installing dental outfits in schools and institutions for relief, repair and restoration of children's teeth. This service reached only a very few, of course, but elicited much favorable comment from teachers and others concerned.

Then came a period of publicity and propaganda exalting the value of tooth brushes, tooth pastes, and dental care for children. It was based on the conspicuous improvement in mental agility—not ability—in conduct, interest, and health of the children which so frequently follows the removal of septic mouth conditions. Elaborate programs of tooth brushing, etc., were developed here and there and reports were soon forthcoming of marked improvement in the children under care, treatment, and observation.

When the charitable instincts of the dental profession had been drawn upon to the limit, efforts were made, often successfully, to place the responsibility for the dental service upon school boards and health departments. This accomplished, the activity became one of public health rather than a charity, which always involves an entirely different viewpoint and mode of attack. It was observed that the cost was 5 times as much to care for 13-year old pupils as for those 6-years old. Therefore, a given sum could care for 5 pupils at the age of 6 and pre-

* Read at a Joint Session of the Child Hygiene and Food, Drugs and Nutrition Sections of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

vent their becoming the 13-year old problems. This idea of service for 6-year olds was established in the Cleveland schools nearly a decade ago. With the money available, it was possible to care for about 26 per cent of the 6- and 7-year old pupils in first grade. It was hoped and expected that parents would see that the care of children's teeth was continued after they were once put into good dental condition.

Some years of experience established the fact that little was being done for the children in the school clinics except those of 6 or 7 years. So large a turn-over is experienced from first to sixth grade that those cared for as first graders are almost entirely lost sight of when we come to examine the sixth grade before sending them into Junior High School. Realizing that it was not practical to secure board of education or health department support sufficient to provide care for teeth of all pupils in all the schools, some other program had to be developed. An analysis of the problem made clear that we had some 78.9 per cent of public school elementary pupils needing attention while 18 years earlier, 97 per cent needed attention. The difference was wholly in the number of cases that had received complete dental care and that almost entirely at the hands of our school dentists. In other words, we had met, through all agencies, only about 20 per cent of the problem.

During the past decade, we have preached milk, fresh fruits, green leaves, and vegetables. While here and there we think we see improved conditions as the result of diet, the extent of improvement among the city's child population is not encouraging. Experimentally, one can get results with proper diet, air, light, rest, exercise and water. Why do we not secure the same results when applied to a community?

Comish in *Standards of Living* throws some light on the matter of income and living standards of the wage earning population of the United States. He shows that 16.7 per cent of families live on a poverty standard or \$1,000 per annum or less; 34.84 per cent live on a minimum subsistence, or \$1,600 per annum or less. In other words, 50 per cent are financially embarrassed all the time. He shows that 44.64 per cent have from \$1,800 to \$4,800 per year per family. These, he says, live on a health and comfort standard, but how many of you think a family of 5 can live in comfort on \$1,800 a year? There remains a group, 3.82 per cent, who live on \$5,000 and up per family. These, Comish says, live in luxury.

It has long been realized that some 20 per cent of the people employ dentists for other than relief of pain. It is generally accepted that approximately 10 per cent are too poor to pay anything for medical and dental service. This leaves 70 per cent who need and want

dental service but are probably not able to pay the usual professional fees. Efforts have been made to refer children to private dentists. It is possible to send about 50 per cent to the dentist, that is, 50 per cent of the parents will say they will take the children to the dentist, but upon checking up we find that but 40 per cent have had service and 60 per cent have not. Analysis indicates that the fundamental reason for the failure to secure dental services for children is economic. There are no surplus funds for such expenses. In other words, the same 20 per cent that have been patronizing dentists will provide dental care for their children and the rest go without. We then have 70 per cent who need, but cannot afford private dental service and should not be given free service. How are these children to be cared for?

There are two urgent problems confronting us: those having badly diseased teeth which require extraction, involving about 40 per cent of the children, and another group of 78 per cent who need fillings or fillings and extractions. The most urgent need seems to be for the removal of septic teeth, since these are an immediate menace to the child's health and happiness.

After much discussion, it became possible in Cleveland to have established 3 extraction surgeries for children on a "Pay-Cost" basis. "Pay-Cost" is a term coined to mean the entire cost of overhead, depreciation and interest on investment, supplies, maintenance and personnel, that is, all the cost of service under organization and system.

It has been found possible to extract teeth for children in these institutions for \$1.75 per case—not per tooth. The average case requires the extraction of about 3.7 teeth. This fee, \$1.75, includes the nitrous oxide anesthesia and the after care. Such service requires for a clinic session of 3 hours, the following staff:

1 Director	Dentist	2 Surgery Nurses
1 Extractor	"	1 Surgery Orderly
1 Anesthetist		1 Recovery Room Nurse
1 Supervisor (relief anesthetist)		1 Sterilizing Room Assistant
1 Admitting Clerk		1 Janitress
1 Preparation Nurse		1 Janitor

All the staff are paid reasonable compensation. They are usually on duty about 4 hours for a 3-hour clinic.

It should be realized that this type of clinic is for service only, not for teaching in connection with a school of dentistry or medicine. Strict asepsis must be and is observed. Thorough organization and attention to details are necessary to effect the economies that make possible a pay-cost service for extraction at \$1.75 per case. The nor-

mal capacity of these clinics is 60 per morning; however, the number often reaches 70 and 80.

Cleveland has 166,000 pupils, in kindergarten to ninth grades inclusive, under organized care. Since 40 per cent of these need extractions, we have 66,400 pupils to care for. As shown above, we may hope for 20 per cent or 13,000 to be cared for by private dentists and 10 per cent or 7,000 in free clinics. This leaves 46,000 to be cared for in pay-cost clinics.

The 3 institutions can care for about 7,200 each, or, collectively, 21,000 or 22,000. In 1929, the 1 such clinic then established cared for 7,290 cases. The 3 now in operation can meet the needs fairly well; that is, they can care for one-half those needing service, which probably is all the school staff can handle. The next step is to provide pay-cost filling service for the great 70 per cent of children so as to save the teeth.

What relation has all this to national problems and nutrition?

We have described a method that has worked in one city and can easily be applied in any other. It is successful because it brings the cost of service within the means of the great mass of self respecting people of meager earning ability. It brings opposition from many sources, of course, but whatever one does provokes adverse comment. The relation to nutrition is just this. We have taught the newer knowledge of nutrition but find meager results. Why? Because it costs money to have fresh, clean air to breathe. It costs money to have exercise and rest under a health promoting environment, and 70 per cent of the people have not enough money to buy all these desirable factors for the promotion of health, including sound teeth.

The immediate problems confronting us are teeth decayed and aching. The needs of today must be cared for while we continue to teach ideas that will make for improvement tomorrow.

The "Pay-Cost Clinic" is the most helpful agency yet employed.

Comparative Dietary Studies of American Children of Nursery School Age*

JET C. WINTERS, PH. D.

*Associate Professor of Home Economics and Director of Nutrition Research,
University of Texas, Austin, Tex.*

THE preschool child has, in late years, received perhaps more than his share of attention. While much of this has been directed toward a study of problems relating to nutrition, very little of it has been devoted to the collection and interpretation of statistical material on food intake. Such investigations are called dietary studies and form, in the main, the basis for our present dietary standards.

In recent years, dietary findings in regard to protein and minerals have been considerably supplemented by balance experiments in which attempts have been made to find the intake of these substances that will bring about the best retention in the body. Also, calorimeter experiments have reinforced the material relating to calories. At best, however, the data upon which our dietary standards for children are based are none too large in amount or too convincing in nature. Nevertheless, these standards, even though unsatisfactory, provide us with criterions for judging the physiological efficiency of a diet, either of an individual child or of a group. Moreover, comparison of the adequacy of the diets of different groups may be made on the basis of the amount and kind of variation from established standards.

It was primarily with the idea of obtaining data on which a comparison of the adequacy of the diet of Mexican, Negro and American children of preschool age might be based that the present investigation was undertaken. In addition, by using figures obtained from children of normal weight only, averages have been secured that may be compared with standards already in existence. Lastly, an attempt has been made to relate the dietary findings to the physical condition of the various groups studied.

The material on which this study is based consists of records of food intake, covering a period of 1 week, for 50 Negro, 50 American

* Read at a Joint Session of the Food, Drugs and Nutrition, and Child Hygiene Sections of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

and 75 Mexican children. The Negro and American studies were made in Austin, Tex., while the Mexican material was obtained partly from Austin and partly from San Antonio. Careful supervision over the records was exercised in order to obtain as great a degree of accuracy as possible. The calorie, protein, calcium, phosphorus and iron content of the daily diet was computed for each of the 7 days and the average per day for each child obtained. Averages were also calculated for each age and sex group of the various nationalities, and comparisons made on the basis of (1) differences in these averages, (2) the variation of the average from the standard, and (3) the percentage of individual diets below the standards in each of the groups. Vitamin content of the diet of the different groups was judged on the basis of the amount of food, rich in the various vitamins, contained in the diets.

TABLE I

AVERAGE DAILY PROTEIN INTAKE IN GRAMS PER KILOGRAM OF BODY WEIGHT OF MEXICAN, NEGRO AND AMERICAN CHILDREN OF PRESCHOOL AGE

<i>Boys</i>	<i>American</i>	<i>Negro</i>	<i>Mexican</i>
2-3 yrs.	3.24	2.89	2.60
3-4 yrs.	2.46	2.70	2.40
4-5 yrs.	2.19	2.53	2.18
Average	2.63	2.37	2.39
<i>Girls</i>			
2-3 yrs.	2.53	2.76	2.70
3-4 yrs.	2.31	2.45	2.62
4-5 yrs.	2.25	2.15	1.89
Average	2.36	2.45	2.40

The groups were fairly evenly divided as to sex, but the different ages were unevenly distributed, and in no case was the age group large enough for the average figures to be more than indicative.

Table I gives comparative results for the protein intake. The average amount of protein consumed daily by preschool children of the 3 nationalities studied was between 2 and 3 gm. per kg. of body weight. This is the amount advocated as desirable by many investigators. There was no great difference in the averages for the nationality groups, but in every case the younger children received a larger amount of protein per unit of body weight than the older ones, and the boys more than the girls.

In spite of the fact that average consumption figures are within the standard, a study of the individual dietaries showed that less than 2 gm. of protein per kg. of body weight was taken by 20 per cent of

the American children, 26 per cent of the Negro children, and 18 per cent of the Mexican children. There was apparently no great difference in the percentage of children suffering from protein deficiency in the 3 nationality groups. Similar figures for age and sex groups showed that a larger proportion of the older groups than of the younger and of the girls than the boys received insufficient protein. This tendency was especially marked among the Mexicans.

TABLE II

AVERAGE DAILY CALORIE INTAKE PER KILOGRAM OF BODY WEIGHT OF MEXICAN, NEGRO AND AMERICAN CHILDREN OF PRESCHOOL AGE

<i>Boys</i>	<i>American</i>	<i>Negro</i>	<i>Mexican</i>
2-3 yrs.	91.80	83.30	78.32
3-4 yrs.	74.19	82.36	73.40
4-5 yrs.	66.80	74.85	61.70
Average	77.60	80.16	71.14
<i>Girls</i>			
2-3 yrs.	78.06	79.54	74.42
3-4 yrs.	74.05	72.46	74.75
4-5 yrs.	65.52	65.48	51.12
Average	72.54	72.49	66.75

Comparative data on calorie intake are given in Table II. Here considerable variation in the nationality groups, as well as in the age and sex divisions within these groups, was shown. The Mexican children had a lower calorie intake than either the Negro or American. Girls, in all cases, had a lower intake than boys. As would be expected, there was a decrease in the calorie intake per unit of weight with age.

The averages were from 12 to 25 per cent below the Holt standards, which were selected for use here because they are stated on the basis of weight, thus giving more definite criterions from which to reckon deviations than those on an age basis. These standards are per kg. of body weight: for 2-3 years, 92.4 calories; for 3-4 years, 88.4 calories; and for 4-5 years, 85.6 calories.

In an effort to avoid overemphasis of calorie deficiency, it was decided to consider as inadequate only diets that were more than 10 per cent below Holt's standards. On this basis, calorie inadequacy was present in 52 per cent of the American, 62 per cent of the Negro, and 66 per cent of the Mexican dietaries. It was also found that only in the Mexican group was the percentage of calorie deficiency larger for the older than the younger children, but that in every group this deficiency was more marked among girls than boys.

Of the minerals necessary for the building and regulating functions of the body, only calcium, phosphorus, and iron are usually considered in a dietary study since it is thought improbable that a diet furnishing a sufficient supply of these elements, which are necessary in large amounts, will not also provide enough of the minerals which the body needs in only small quantities. Table III gives the average daily intake in grams for calcium, phosphorus and iron.

A study of these averages showed that the Negro and Mexican intake of calcium was not much more than half that of the American. This large difference was not apparent in either phosphorus or iron,

TABLE III

AVERAGE DAILY MINERAL INTAKE IN GRAMS OF MEXICAN, NEGRO AND AMERICAN CHILDREN OF PRESCHOOL AGE

<i>Calcium</i>			
<i>Boys</i>	<i>American</i>	<i>Negro</i>	<i>Mexican</i>
2-3 yrs.	.9756	.6021	.6224
3-4 yrs.	.9269	.5678	.6103
4-5 yrs.	.8492	.5760	.4868
Average	.9172	.5819	.5731
<i>Girls</i>			
2-3 yrs.	.7968	.6422	.5199
3-4 yrs.	.6721	.5893	.5280
4-5 yrs.	.8534	.4657	.5095
Average	.7741	.5657	.5191
<i>Phosphorus</i>			
<i>Boys</i>			
2-3 yrs.	.9912	.8030	.9489

4-5 yrs.	.9871	.7719	.8509
Average	.9768	.8031	.8801
<i>Girls</i>			
2-3 yrs.	.7804	.7547	.9913
3-4 yrs.	.7560	.7214	.9531
4-5 yrs.	.9101	.6808	.7560
Average	.8155	.7189	.9001
<i>Iron</i>			
<i>Boys</i>			
2-3 yrs.	.00711	.00700	.00512
3-4 yrs.	.00598	.00712	.00615
4-5 yrs.	.00797	.00706	.00538
Average	.00702	.00706	.00555
<i>Girls</i>			
2-3 yrs.	.00575	.00725	.00480
3-4 yrs.	.00588	.00677	.00489
4-5 yrs.	.00676	.00585	.00434
Average	.00613	.00662	.00468

the phosphorus intake of the American group being only slightly higher than either the Negro or Mexican, and iron intake slightly lower than that of the Negro, but considerably higher than that of the Mexican. In all 3 groups, the average intake of girls, for each of the minerals, was considerably lower than that for boys. There was a general tendency for the calcium and phosphorus intake to be highest for the youngest group. This propensity was not found in iron.

According to Sherman¹ and other investigators, the large demands of the growing child for calcium and phosphorus make necessary an intake of at least 1 gm. per day of each of these minerals. No such definite statement as to iron requirement is available, but Rose² suggests that a child needs at least as much iron per unit of calorie requirement as an adult, i.e., 0.0005 gm. of iron for every 100 calories. On the basis of the above mineral standards, and considering as inadequate only diets that were more than 10 per cent below the standard, it was found that calcium inadequacy existed in 50 per cent of the American, 90 per cent of the Negro, and 96 per cent of the Mexican dietaries; phosphorus in 38 per cent of the American, 74 per cent of the Negro, and 64 per cent of the Mexican dietaries; and iron in 50 per cent of the American, 32 per cent of the Negro, and 66 per cent of the Mexican dietaries.

In a general way it may be said that the percentage of diets deficient in calcium and phosphorus was almost twice as great for Negroes and Mexicans as for Americans, but the larger percentage of calcium inadequacy in the American diets makes the calcium deficiency of the Negro and Mexican diets much more outstanding than that of phosphorus. Negro children were apparently much less likely to suffer from iron deficiency than either American or Mexican, the latter faring worst of all in this respect.

The percentage of calcium inadequacy was found to be fairly evenly distributed through the various age groups in American and Negro diets, but to be much greater among the older than the younger Mexican children. The distribution of iron and phosphorus deficiency seemed to be fairly even in the various ages for all 3 groups. Again, in all groups a larger percentage of girls than boys suffered from deficiency in all 3 of the minerals.

In the American group the mineral deficiencies were mostly the result of calorie deficiency; i.e., there were very few cases of adequate calories accompanied by inadequate minerals. In the other groups, however, adequate calorie intakes were found along with inadequate calcium or phosphorus or both. The difference in the calcium content of the diets of the 3 groups is to be explained almost entirely on

the basis of the difference in the amount of milk used. The average amount of milk taken by the American children was slightly more than $2\frac{1}{2}$ cups per day, while for both the Negro and Mexican groups it was somewhat less than $1\frac{1}{2}$ cups. The low figures for iron inadequacy in the Negro group are probably explained by the wide use of "greens." Greens appeared on only 3 of the Mexican diets.

Taking into consideration the 5 food factors discussed, protein for every group was the one least likely to be deficient. While calcium was outstandingly deficient in Negro and Mexican diets, American diets were no more likely to be inadequate in this than in calories or iron. Calculation of the average number of deficient factors for each group shows this to be 1.8 per child for the American, 2.6 for the Negro and 3.4 for the Mexican.

In order to obtain figures that might be compared with existing standards, the average intake for each of the 5 food factors for children of normal weight only was calculated. The results showed, briefly, that the averages for protein and iron were within the standards, but that the average calorie intake was from 10 to 15 per cent below, the average calcium intake approximately 33 per cent below, and the average phosphorus intake almost 20 per cent below standards. The maintenance of weight does not, of course, mean the maintenance of health.

An attempt will be made to discuss and compare the vitamin content of the diets on the basis of the amounts of vitamin-rich foods contained therein.

For vitamin A, milk, butter, egg yolk and leafy vegetables are depended upon. In none of the diets was there enough milk to furnish, unsupplemented, a sufficient amount of this vitamin, but the Mexican and Negro diets required much larger supplements than the American. Butter, however, was used in larger quantities in the American than in either of the other groups. A study of the diet of Mexican families showed that a low income group used only $\frac{1}{4}$ lb. per week per family, and a higher income group only $\frac{1}{2}$ lb. Eggs were used in about equal amounts by Negro and American children, but much less than once a day, which is the prescribed amount. They are evidently widely used by the Mexicans, as the study referred to above showed from 2 to 3 eggs per family daily.

The "greens" used by the Negroes helped to supplement their diet in regard to this vitamin, a supplement lacking in the Mexican diets. Fifty per cent of American children had been given cod liver oil with more or less regularity, thus enriching their diet immeasurably in vitamin A. Cod liver oil therapy was practically unknown among both

the other groups. On the whole, it seemed that the diet of American children ranked first in regard to A, that of Negroes next, and Mexicans last.

It is thought that none of the groups were so apt to suffer from B as from A deficiency, but that a wider variety of fruits and vegetables and the use of larger amounts of milk and whole grain rather than milled cereals gave the American diets a better content of B than either the Negro or Mexican. The Mexicans use large amounts of cereal, but to a great extent they have substituted white flour for whole corn products which in the past were so extensively depended upon. This practice is undoubtedly cutting down their B supply. Neither Mexicans nor Negroes used whole wheat to any appreciable extent. Not one of 144 Mexican families included in a dietary study bought whole wheat flour or bread during the week which the study covered. Whole wheat bread appeared on only 2 of the diets for Negro children, but was used almost exclusively in the American diets. To offset a possible B deficiency, there was the wide use of beans, potatoes and tomatoes, all good sources of this vitamin, by both Mexicans and Negroes.

Fresh fruits and raw vegetables are splendid sources of Vitamin C. These appeared with much more regularity in the American than the other diets. However, spinach, cabbage, and tomatoes were present with considerable frequency in the Negro diets and potatoes were a staple. Potatoes and tomatoes were also widely used by Mexicans as were onions, another good source of C. In spite of the restricted nature of the Negro and Mexican diets, it is thought that they contained fair amounts of C, and that there was less danger of a lack of this vitamin than of either A or B.

Unless obtained by special therapy, the supply of vitamin D depends largely upon sunshine. Whether there is any difference in the amount of sunshine to which the children in the various groups are exposed is not known. It is possible that Negro and Mexican children are in the sunshine for longer periods than American children, and that, because of less clothing, the ultra-violet rays have better access to their bodies. However, greater pigmentation of the skin might be expected to offset this advantage. Since special therapy was employed to provide a large proportion of American children with this vitamin, i.e., cod liver oil or viosterol, they were probably better supplied than children of the other groups.

So little is known about the food content of G that no effort will be made to compare the diets in regard to this vitamin.

Summarizing briefly, it may be said that the group of American

preschool children, although far from being supplied with adequate amounts of the necessary food elements, were less inadequately nourished than the children comprising the Negro and Mexican groups, and that Negro diets were somewhat more adequate than Mexican. There was a fairly definite tendency, especially marked in the Mexican group, for the younger children to be better fed than the older, and a decided tendency for boys to be better fed than girls. The most outstanding inadequacies were those of calcium and vitamin A in the Negro and Mexican diets. These are probably to be accounted for on the basis of the small amount of milk used. A considerable number of the children were maintaining weight on diets that were appreciably below standard in one or more factors.

Environment and diet are so interrelated in their effect upon the physical condition of the child that caution must be used in attempting to separate them as causative factors. It is felt, however, that this study would be incomplete without some attempt to point out probable relationships, or the lack of them, between the calculated dietary deficiencies and the physical conditions existing in the groups studied.

Weight for height and age, though far from a perfect index, is often considered the best single criterion of a child's health, and calorie intake is thought to be more directly related to the maintenance of normal weight than intake in any other factor. From the data on calories already given, a large percentage of underweight in each of the groups might be expected. Using the Woodbury standards and considering more than 7 per cent below normal as underweight, it was found that 96 per cent of the Mexican, 94 per cent of the American and 66 per cent of the Negro children were maintaining normal weight. Not knowing how to explain this disconcerting result it was decided to obtain underweight statistics on larger groups of children, in order to see if the above percentages were representative. Data on 80 American preschool children that had been admitted to the nursery school connected with the university in Austin showed 17 per cent of them to be underweight, and the physical examination records of 200 Mexican preschool children in San Antonio showed 32 per cent of underweight. No data on a larger Negro group were available.

In view of the effect of mineral deficiencies on the growth of the skeleton, it was thought interesting to compare the percentages below, within and above normal height for age in the 3 groups. This was done by using the Merrill-Palmer figures which give a normal range of height for age. In the Mexican group 86 per cent of the children were below this range, 14 per cent within, and none above; in the Negro group 27 per cent were below, 46 per cent within, and 27 per cent

above; in the American group 17 per cent were below, 43 per cent within, and 40 per cent above. Many other factors than diet, notably heredity, are important in determining height, but it is not impossible that mineral deficiencies were to some extent responsible for the above differences.

Since calcium deficiency was so outstanding in the Negro and Mexican diets, it was obviously logical to look for physical results of this inadequacy. However, present-day literature on the subject does not make very clear what results are to be expected from low calcium intake, unaccompanied by vitamin D deficiency. Calcium, vitamin D, and vitamin C are all said to be necessary for the production of good teeth. No data on teeth are available for a large group of Texas-American children, but a survey of Kansas preschool children was made by Rypins,⁵ who reported that of 1,197 children, 27.2 per cent had dental caries which averaged over 1 decayed tooth for each mouth examined, and almost 4 decayed teeth for each of the carious mouths, and that of the teeth erupted, 6.3 per cent were carious. Comparable figures for 200 Mexican children show that 41 per cent of the children had decayed teeth with an average of 1.2 decayed teeth for each mouth examined and 3 decayed teeth for each of the carious mouths. Of the teeth erupted, approximately 7 per cent were carious. If comparison between these 2 groups is valid it shows a larger percentage of bad teeth in the Mexican group. No data on a group of preschool Negro children are available, but Sterling⁴ in a study made in Atlanta, Ga., of 5,000 Negro children of school age, found that only 35 per cent had carious teeth. He states that this figure compares very favorably with figures for white children.

The extent to which "signs" of rickets appear in the carious groups might be taken as indicative of differences in vitamin D supply. Well developed cases of rickets seldom appear in this climate, but a definite number of children show signs of early rachitic lesions, such as enlarged wrists and ankles, Harrison's groove, depressed ensiform, etc. Physical examinations of 200 Mexican preschool children showed that 19 per cent had rachitic signs other than flat-feet, bow-legs and knock-knees, while only 7 per cent of the 75 children admitted to the University Nursery School showed definite signs of rickets. The percentage of flat-feet, bow-legs and knock-knees was large in both groups, but these abnormalities, in the absence of other signs, are not considered as definitely indicative of rickets. Again no data on a Texas-Negro group are available.

Lastly, marked deficiency in vitamin A was found to be characteristic of Negro and Mexican diets. Slow growth and a lack of re-

sistance to infection have been found to result from a low intake of this vitamin. Lowered resistance to infection is characteristic of Mexicans and Negroes, both children and adults. Fully twice as many Mexicans as Americans die of tuberculosis, and the percentage of Mexican children under 2 years of age that die from diarrhea, presumably caused by infection, is more than 4 times that of American; above 2 years of age it is twice as great. These differences are no doubt partly due to increased exposure to infection, but it is entirely possible that low vitamin A intake, together with other food deficiencies, is largely responsible.

Although the data on physical condition are too inadequate to admit of a striking demonstration of the relationship of diet to physical well-being, it is thought that evidence of such relationship is not entirely lacking.

NEW MONTREAL HARBOR BRIDGE OVER ST. LAWRENCE RIVER SHIP CHANNEL

Effect of Diphtheria Immunization upon Case Incidence and Mortality*

C. H. KINNAMAN, M. D.

Epidemiologist, Kansas State Board of Health, Topeka, Kan.

THE control of diphtheria in Kansas is a problem that has to do with 1,852,114 individuals who are irregularly distributed over an area of 81,774 square miles. Thirty-three per cent of the population is urban and 67 per cent rural. The population in age groups under 20 is as follows:

TABLE I

Under 1 year.....	30,684
1-4 years.....	154,950
5-9 years.....	185,047
10-14 years.....	180,557
15-19 years.....	170,840
Total.....	722,078

For 1920, before any immunization work was started, 84 per cent of the reported cases of diphtheria occurred in the age group below 20, and 16 per cent above. The percentages under 20 are shown in Table II.

TABLE II

Under 5 years.....	17.0 per cent
5-9 years.....	37.7 per cent
10-14 years.....	21.2 per cent
15-19 years.....	8.1 per cent
Total.....	84.0 per cent

In 1921, Kansas had the most severe epidemic of diphtheria in its history; 7,849 cases were reported with 382 deaths.

The first toxin-antitoxin administered on a county-wide basis was in Wabaunsee County with a rural population of 10,710. The largest village is Alma, the county seat, with a population of 771. Diphtheria being epidemic in this county, the county commissioners, who are the county board of health, agreed to furnish the toxin-antitoxin to each

* Read before the Epidemiology Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

Health, June 30, 1930, in "The Diphtheria Campaign to Date," we note the cases and deaths for 10 years:

COMPARATIVE CASE FATALITY RATE FOR NEW YORK CITY AND STATE OF KANSAS

	New York	Kansas
1920	5.9 per cent	4.9 per cent
1927	5.3 " "	6.9 " "
1929	5.4 " "	7.3 " "

For New York City, the case fatality rate has shown a decrease while in Kansas the rate has gradually increased. We have observed in Kansas that diphtheria is apparently of a more virulent type as the number of immunized children is increased. Health bulletins from other states call attention to the apparent increase in their case fatality rate following the immunization of large numbers of children.

In culturing 20,000 school children over the State of Kansas, it was found that the percentage of carriers was practically the same in immunized groups as in counties where immunization has been neglected. Our observations are that the immunized carriers pass diphtheria organisms of the most virulent type to the non-immunized child with the result that the case fatality rate is increasing each year among non-immunized children who contract diphtheria. Also, the adult population, a percentage of which has not acquired a natural immunity, are contacts with immunized children who are carriers. In 1920, 16 per cent of the reported cases occurred in age groups above 20. For 1929, 73.8 per cent were in the age group under 20 and 26.2 per cent were 20 or more, showing a decrease of 10.2 per cent below, and an increase of 10.2 per cent above 20 as compared to the reported cases in Kansas for 1920, as shown in Table V.

TABLE V

Year	Under 5 years	5 to 9	10 to 14	15 to 19	20 or over
1920.....	17.0	37.7	21.2	8.1	16.0
1929.....	20.6	32.2	13.4	7.6	26.2

These figures show 2.6 per cent increase under 5 years, 5.5 per cent decrease 5 to 9, 7.8 per cent decrease 10 to 14, 0.9 per cent decrease 15 to 19, and 10.2 per cent increase 20 years or more.

At present, 60 per cent of the children from 1 to 14 have received toxin-antitoxin. We believe there are other factors in addition to toxin-antitoxin immunizations which have played an important part in decreasing diphtheria cases and deaths, such as:

1. The physical examination of school children with the increased correction of defects relating to the nose and throat. Many children with defects of this type have been found who remain carriers of virulent diphtheria organisms for many months, medicinal treatment being of no value in clearing the carrier. Only by a surgical correction were these children made negative.

2. In 1922, the diphtheria quarantine period was extended to 16 days, with release at the end of this period only after 2 consecutive negative cultures 48 hours apart, and culture of all other members of the household. This rule has demonstrated that it prevents the release of numerous persistent carriers.

3. The culturing of contacts, especially in the schools, the removal and quarantine of the carrier for the same period as an active case with release under the same conditions.

The detection of a carrier is comparatively simple, but the problem of returning negative nose and throat cultures is much more difficult. If a carrier has diseased tonsils, they should be removed and any other pathological condition of the nose and throat corrected.

We have mentioned the county-wide immunization of the children of Wabaunsee County in 1921. This same plan was again adopted in 1926 for the non-immunized children who had entered school the past few years. After this second immunization work was completed, a careful check showed 95 per cent of the school population immunized. In October, 1929, a representative of the Division of Communicable Diseases checked the schools of the county to discover the percentage of immunized children in the various school districts. Only 52 per cent of the attendance was found to have received the toxin-antitoxin immunization. Every school district having non-immunized children arranged for the free immunization of pupils not having previously received the treatment. The results of this survey stress the importance of a yearly check on the number of pupils immunized, as even in this rural community the population shows a number of changes each year.

The Kansas diphtheria death rate per 100,000 population was in 1920 14.6; 1926, 2.7; 1929, 3.6.

The conclusions from these observations over this 10-year period are:

1. When 50 per cent or more of the children are immunized in a rural community, the non-immunized child is in greater danger of a fatal termination if it contracts diphtheria than in counties where no immunizations have been done.
2. Fatal cases are showing an increase in children under 1 year of age with an increased morbidity rate. The percentage of adult cases reported has shown an increase each year.
3. The treatment of diphtheria has improved during this period because physicians are giving 10,000 or more units of antitoxin. In the past 3,000 and 5,000

units were more often given as the initial dose. Adequate dosage of antitoxin given early will reduce the case fatality rate.

4. Many immunized children in rural districts are carriers of highly virulent diphtheria organisms.

5. Diphtheria shows an increased percentage of reported cases in the age groups above 20.

6. To be successful in the eradication of diphtheria, the preschool group must be immunized. Babies should be immunized when they reach the age of 6 months.

Maternity Benefits in Sweden

THE question of maternity benefits has been receiving considerable attention in Sweden in recent years. For a number of years there has existed in that country a system of voluntary sickness insurance, which also included provision for maternity benefits. But because of the voluntary feature of the system, large numbers of women were left without insurance; to remedy this situation it was decided several years ago to make insurance compulsory, and a bill to that effect was introduced.

Early in 1931 a new bill, prepared by the Department of Social Welfare with the collaboration of specially invited experts, was introduced into the Riksdag. The new bill provides for insured women midwife's services and a maternity benefit of 2 kronor (53.6 cents) per day payable for at least 30 days, and for at least 42 days in the cases of women workers who are by law forbidden to return to work earlier than 6 weeks after confinement. Nearly one-half of the above benefit is to be supplied by the national treasury; the rest by the sick funds. An unusual feature of the bill is maternity benefits and midwife's care for non-insured women whose income is below a certain amount. The cost of this aid is to be met entirely by the national treasury.

Another government bill introduced this year makes provision for prenatal and postnatal care. The work is to be started at first only in four provinces. The main purpose of this work will be teaching of hygiene to mothers by specially engaged physicians and nurses. Arrangements are also to be made for coöperation between the midwives in public service and the social welfare authorities. The work is considered as a supplement to the existing maternity welfare work in Sweden.—*Sociala Modellanden*, Stockholm, No. 3, 1931; *Tidsskr. f. d. Barnavård och Ungdomsskydd*, Stockholm, Nos. 1 and 2, 1931, and translator's comments.

A Water-Borne Typhoid Fever Outbreak*

With Unusual Epidemiological Features

FREDERICK W. SEARS, M. D., F. A. P. H. A.

District Health Officer, Syracuse, N. Y.

SENECA Falls is a village of about 7,000 inhabitants, situated in the heart of the Finger Lakes Region of New York, and lies about 3 miles west of the northern end of Cayuga Lake and 9 miles east of the northern end of Seneca Lake.

Cayuga Lake, from which Seneca Falls receives its water supply, is about 37 miles long and from 1 to 3 miles wide, having a total area of about 60 square miles. The total population on the water shed is about 30,000, including the city of Ithaca which is situated on the southern end of the lake, has a population of about 19,000, and drains its raw sewage directly into the lake.

Both Cayuga and Seneca Lakes form a part of the New York State Barge Canal system. Mud Lock is situated at the outlet of Cayuga Lake through which all boats enter and leave this part of the canal system. Seneca River, now a part of the Barge Canal, flows into Cayuga Lake near Mud Lock. The current of the water normally is northward, joining the main portion of the Barge Canal at Montezuma. The level of the lake is maintained by a spillway located near Mud Lock. Seneca River receives the untreated sewage from Geneva, Waterloo, and part of Seneca Falls, a combined population of about 12,000, and is at all times highly polluted.

The water supply of the village of Seneca Falls is pumped from Cayuga Lake through a 16" pipe into pressure filters and from these it goes directly into the water system, composed of about 22 miles of iron pipe varying from 4" to 14" in diameter. The average daily amount of water pumped is 1,500,000 gallons. The intake pipe is about 3 miles south of the outlet.

With the normal flow of the lake toward the outlet the filter system has given fairly adequate protection to the water supply, although colon bacilli have been frequently present in the filtered water at certain times of the year.

* Read before the Epidemiology Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

The closing of the spillway of the Barge Canal creates a menace to the water supply of the village of Seneca Falls. This happens especially in the spring of the year when the level of the lake is high. At such times the water from Seneca River which forms a portion of the Barge Canal flows southward, reaching a point near and beyond the intake pipe of the Seneca Falls water system.

In the month of January, 1918, there was a sudden outbreak of diarrhea affecting a considerable number of people in the village of Seneca Falls. Investigations by the State Health Department showed that this reverse current from the northern end of the lake was probably the cause of the outbreak. Following this investigation the water board was urged to apply liquid chlorine constantly to the filtered water, and an apparatus was purchased soon afterwards, but not put in use.

In March, 1920, a similar, but more severe than the former, outbreak occurred under like circumstances. It was estimated that between 600 and 700 people in the village of Seneca Falls were affected with diarrhea and dysentery. The first case of this outbreak which lasted about 10 days and ceased about the time the gates were opened March 24, occurred March 15. A chlorinating apparatus was then installed and has been kept more or less constantly in use. Regular tests following this installation showed the water to be of a satisfactory quality.

A small number of typhoid fever cases followed both the 1918 and 1920 outbreaks of diarrhea.

On August 30, 1920, I received a telephone message from the Health Officer of Seneca Falls stating that typhoid fever was developing in a small portion of the village. This outbreak was very puzzling to him because the only common source of food or drink for the reported cases was the water supply, and inasmuch as tests made at the pumping station showed it to be of satisfactory quality, with no gas forming bacilli, he was unable to explain the outbreak, and I was requested to assist him.

I immediately went to Seneca Falls and learned that the outbreak had been preceded by cases of severe diarrheal trouble, one death from this cause having occurred August 28. This led me to believe that the outbreak was water-borne, and the officials connected with the water department were brought into conference and all facts concerning the outbreak were freely discussed.

The part of the village involved was a southwest corner adjacent to a large manufacturing plant employing from 700 to 900 people. This plant had an independent water supply from two sources, one a

deep well which furnished water for drinking purposes, and the other water pumped from the Seneca River part of the Barge Canal into large receiving tanks, and used only for flushing and cooling purposes. This plant was connected with the village water system at 2 points: one at Chapel Street and one at Heath Street. Single check valves served to prevent the back flow of water from the plant into the village system. This supply was not supposed to be used by the plant except in case of fire, but connections were made in order to secure lower fire insurance rates.

I also learned that the tanks containing water from the polluted stream were filled about August 9 and about that time there had been complaints from residents of the section of the village under question that the water was turbid. Little attention was paid to this as it was thought to be due to blind ends in the water system. Suspicion was immediately thrown upon the efficiency of the valves in the connection between the village and the manufacturing plant. It was ordered that they be immediately investigated.

Early the following morning these were uncovered and a hole was discovered in the one at Heath Street. It was estimated that about 7,000 gallons of water could pass through the hole. A hole was drilled in the pipe between the plant and the village water system and a pressure gage applied, which showed that the pressure in this pipe was greater than that in the adjacent village water system. Samples of water were taken from the hydrants in the neighborhood and were found to be highly contaminated with organic matter and other impurities. The connections between the plant and the village manufacturing plant were sealed and the water from the plant was shut out. Samples were again taken and the water was found to be free from pollution.

The section involved is on a lower level than the rest of the village and the supply is through 8" pipes from the higher level. It therefore was not possible to maintain a higher pressure in the village mains than in the pipes from the higher level. The system remained free from pollution and the water was found to be pure. People in this section were not affected by the disease.

The pipes connecting the plant and the village were sealed but a large hole was discovered in the pipe at Heath Street.

From the beginning of the epidemic 6 cases of typhoid fever were reported. These 6 had either lived or been in the village. In fact all of the cases used water in this particular section.

give to
but in
abstract,
Sil, 1931.

A thorough investigation of the milk supply showed that of the 8 milk dealers the percentage of milk sold to the people infected corresponded very closely to their total distribution, with 1 exception whose patrons resided largely in this section.

The manufacturing company employed experts for the purpose of showing that this epidemic was milk-borne. These efforts, however, were unconvincing and only tended to emphasize the correctness of our first suspicions.

The problem of handling such a large number of typhoid fever cases was a serious one. Seneca Falls had no adequate hospital facilities nor could we secure them in the nearby cities. It became imperative for us to make some provision for a temporary hospital. Inasmuch as this happened soon after the close of the World War, very few nurses were available. The Health Officer applied to the Red Cross for assistance and several possibilities for a temporary hospital were considered.

Following a conference on September 6, we were able to secure a portion of the Episcopal church which seemed to be admirably adapted to our needs. Beds were obtained from the barracks at Oswego, and were rapidly converted into practical hospital beds. Screens were installed in all windows and excellent facilities for cooking made available. On September 7, 5 patients were admitted. A total of 34 were cared for at the hospital during the outbreak. The total hospital days was 836. Nineteen nurses were employed, 10 for day and 9 for night duty. Care was given not only to the hospital patients but a visiting nurse service was established for those treated at their homes. The number of home visits was 467. In addition, clinics for free inoculation with antityphoid vaccine were established, and 375 people were given these preventive treatments.

The total cost of maintaining this hospital was \$5,309.60. The largest item was \$2,568, for nursing service.

There were 5 deaths, 3 in the hospital and 2 outside. The average age of those infected was 29.4 years.

COMMENTS

As the spoor of the wild animal unerringly leads the hunter to his prey so it is that certain epidemiological data just preceding the outbreak of typhoid fever blaze for us the trail which we shall follow in speedily tracing its source.

The average age of the victims gives us a strong hint as to whether it is a milk-borne or water-borne outbreak, but what is of greater value in tracing water-borne outbreaks is the knowledge that dysentery and

diarrhea have immediately preceded the typhoid cases in the same locality, and it was this fact that placed us on the water-borne trail in spite of the fact that only a small area of the village was infected, and the only food or drink which was partaken by all of the victims was the water from the common village supply. By following this trail we were able to locate the source within a few hours and check further infection.

The excellent service rendered by the Red Cross undoubtedly prevented a much higher death rate. I believe no well organized hospital could have given more adequate and efficient care than was given by the Red Cross service in this temporary hospital.

CONCLUSIONS

Cross-connections between a city water supply and a water supply of doubtful purity for manufacturing plants or other purposes should never be tolerated. No mechanical device for protection is fool-proof, and all devices designed to protect municipal water supplies against water of questionable purity have been legally eliminated in New York State since July 1, 1926.

BCG Vaccination

MY experiments provide no confirmation of the conclusion of Wilbert (Director of the Laboratory, Pasteur Institute, French Guinea) that monkeys can be completely protected against a virulent experimental or familial infection by vaccination with BCG given by the mouth or inoculated into the tissues. Some of the monkeys fed or inoculated with BCG showed no higher resistance to the test bacilli than the untreated controls. In other monkeys the disease produced though progressive was more protracted in its course and, but not always, less in extent than in the controls. . . . The strain of BCG used in these experiments can produce local lesions in the rhesus monkey, but these are always benign and do not lead to generalization.

BCG given by the mouth can pass through the mucous membrane of the alimentary canal into the adjacent glands and also gain access to the blood stream.

Vaccination with BCG, whether by feeding or by injection, has failed to give to monkeys the complete protection against tuberculosis reported by Wilbert, but in some instances may have produced a low grade of relative immunity.—Abstract, *Special Report Series, No. 152*, A. Stanley Griffith, Medical Research Council, 1931.

Inter-Chamber Health Conservation Contest*

LEROY A. LINCOLN

Chairman of the United States Chamber of Commerce Health Conservation Contest Committee

THE people of our country have, in large part, come to realize the importance of public health administration. They see it as a vital matter not only for the individual but for the community as a whole. The increase of population and the rapid growth of our cities have made it imperative that we control epidemics and protect their citizens, in every way science makes possible, from unnecessary diseases and premature deaths. This is a matter of the first importance to business and to the whole economy of the nation. When people are sick they are unable to do their work; there is loss in production and expense in treatment.

It is not ordinarily realized that the great advances which have been made in public health work are very recent. The expectation of life or the "average-after-life-time at birth" has increased about 18 years in the last 100 years. It was 41 years around 1930, and is now close to 59 years. But 10 of those 18 years have been gained since the beginning of the present century. In the earlier period there was an accumulation of knowledge of how diseases are caused and spread; in the last 3 decades we have been applying such knowledge to human betterment. The organization of public health administration, as a function of government, is relatively new. We are only now learning what great advances in human welfare are possible when the basic discoveries of modern medicine are generally applied. The public wants the benefits of the scientific discoveries and it is willing to tax itself within reason toward these ends.

There is still much to be done in the field of preventing disease and premature death. Experience not only in this country but all over the world has demonstrated that public health is purchasable and that expenditures made in this direction pay the best kind of dividends to the community.

And so it was that the Chamber of Commerce of the United States,

* Presentation of Awards to the winning cities in the 1930 Health Conservation Contest at the Annual Meeting of the Chamber of Commerce of the United States at Atlantic City, N. J., April 28, 1931.

two years ago, announced an inter-chamber health conservation contest. The Health Committee appointed by the Insurance Department Committee of the Chamber was convinced that many cities could reduce serious economic losses through improved public health organization. It was also believed that competition between cities would arouse interest over the whole country and result in better conditions. It was for this reason that the Inter-Chamber Health Conservation Contest was launched. The work was carried on under the auspices of the National Chamber with the coöperation of the American Public Health Association.

The first announcement in 1929 received an immediate and encouraging response from the local chambers of commerce. There were 140 cities in the first enrollment; in the second year, which has just closed, the enrollment was 208 cities. The entries geographically have been very widespread. Cities in 43 states, the District of Columbia and the Hawaiian Islands were represented this year. Twenty-one per cent of the cities are in the eastern section; 38 per cent in the central; 29 per cent in the southern; and 14 per cent in the western. The total population represented in the 208 cities was over 25 millions. On every side, the work of the contest was met with satisfaction.

The health officers, the local chambers, and the local business men who have interested themselves have appreciated to the full the value which the contest has had for their cities, the service which the field workers have rendered, and the excellent results which have followed.

The best proof of the favorable influence of the contest is that every city winning in this year's contest which had competed the year before showed a decided increase in its health score, as great as 30 or 40 per cent in some cases. While some of this improvement in the score may be due to better record keeping, there seems to be no doubt that distinct and definite advances have been made in community health accomplishments. Ninety-four per cent of the cities submitted schedules this year which showed from a moderate to a well-marked increase in score for public health services rendered and public health improvements effected, and this in spite of the fact that the requirements were made more exacting.

One of the important factors in this contest is the opportunity it has afforded to influential business men to serve on public health committees of local chambers of commerce and in this way to become acquainted with the local health problems. The contest has served to interest from 2,000 to 3,000 active and progressive business men to learn about their health departments, to see how they are administered, whether they are getting enough public funds, whether their

staffs are adequate and well trained—in short, to have a more sympathetic understanding of local needs.

The life insurance companies which are helping to finance the field work of the contest are cognizant of its value. They see the importance of the fact, look upon it as a real advance that the cities of the country are entering this contest, and are willing to study their health needs in a uniform manner, to follow standard practices, to increase budgets wherever necessary, and especially that they are securing the support and good will of their business men as represented in their local chambers of commerce.

In the year 1930, cities entered in the competition were divided, according to definite population groups, into 6 classes, thereby limiting each city's competition with those of comparable population. Following the winning city, the next 5 in each group have been given honorable mention and an engraved certificate will be sent to the local organization and the health department representing each city in the contest.

The winning and honorable mention cities in the respective groups are as follows:

CLASS I. (Cities over 500,000 population)

Detroit, Mich.
Milwaukee, Wis.
Philadelphia, Pa.
San Francisco, Calif.
Baltimore, Md.
Buffalo, N. Y.

CLASS II. (Cities 250,000–500,000 population)

Newark, N. J.
Cincinnati, O.
Rochester, N. Y.
Kansas City, Mo.
Denver, Colo.
Memphis, Tenn.

CLASS III. (Cities 100,000–250,000 population)

New Haven, Conn.
Syracuse, N. Y.
Yonkers, N. Y.
Hartford, Conn.
Utica, N. Y.
Reading, Pa.

CLASS IV. (Cities 50,000–100,000 population)

Racine, Wis.
Harrisburg, Pa.
Evanston, Ill.
East Orange, N. J.
Durham, N. C.
Pasadena, Calif.

CLASS V. (Cities 30,000–50,000)

Alhambra, Calif.
Salem, Ore.
White Plains, N. Y.
West Orange, N. J.
Watertown, N. Y.
Fargo, N. D.

CLASS VI. (Cities under 30,000 population)

Chestertown, Md.
Sidney, O.
South Orange, N. J.
Albany, Ga.
Palo Alto, Calif.
LaSalle, Ill.

LIFE MEMBERSHIP

THE life and value of any scientific organization depend upon the quality and permanence of its membership, as well as upon the contributions which they make to the particular science to which the organization is devoted.

The American Public Health Association will hold its Sixtieth Annual Meeting in Montreal in September. It is, we believe, the oldest public health organization in the world, and one needs only to glance over its transactions to be assured that its membership has always included the leading men in the public health profession in the four countries whose citizens are eligible. Further study will show that every branch of public health has had expert consideration from the time its founder, the late Dr. Stephen Smith, published his epoch-making studies, up to the present. The Association has never gone out into the highways and byways in an attempt at numbers, though its doors have always been open to all who are seriously interested in public health or have made contributions to this end along any of the many lines embraced. In spite of the many special societies, the Association has always held its own as the parent organization. Its files contain discussions of every subject relating to public health brought up to date from year to year by experts.

There is danger of being swamped financially and otherwise in the

multiplicity of scientific societies, the pressure from which has been felt by all.

In 1928, constitutional provision was made for Life Membership in the Association to which any member or fellow is eligible. While membership in the Association is an honor, and fellowship takes recognition of the fact that one has been a member in good standing for a number of years, life membership is a still higher privilege, since it is granted only on the recommendation of a special committee which examines the qualifications and character of the applicant.

There are advantages to the holder of such membership as well as to the Association. The life member has no annual dues and no subscriptions to the JOURNAL of the Association to meet. His standing is assured in good times as well as those of depression. He has proved to the world his right to membership in this oldest of all organizations of its kind, and has shown the highest type of professional spirit.

From the standpoint of the Association, there is relief from the expense incidental to sending out annual bills and making collections. Further, it gives to the Association a permanent fund upon which it can count—an endowment, as it were—from those of its members who appreciate what it has done for them and the profession in which they are most interested.

Several very pleasing suggestions have been made by the committee in charge of this matter. Health officers and other health workers may be proposed by their associates or communities for Life Membership in honor of a Christmas, a birthday, an anniversary, or retirement. As such, it is a certificate of honor, as well as a recognition of faithful service.

Let us make the Sixtieth anniversary meeting of our Association memorable by the election of a large number of life members, and in so doing, renew our pledge to the world for the betterment of mankind and his environment.

LEE K. FRANKEL, PH.D.

LEE K. FRANKEL, President of the American Public Health Association in 1919, died in Paris on Saturday, July 25, in the 64th year of his age. He had been in Europe for 3 months conducting a study of social insurance and of the effect of the various insurance systems on the health and well-being of the people. In his death, the public health movement has lost a leader of distinction. Few did more than he to advance the movement along so many lines during the last quarter of a century.

Frankel's service was probably of the greatest value in the field of public health education. As the head of the Welfare Division of the Metropolitan Life Insurance Company since 1909, he enjoyed an extraordinary opportunity to spread the gospel of personal health and of community hygiene to every corner of the United States and Canada. Very early, he created an extensive popular literature which covered virtually every one of the communicable diseases and, in fact, every important aspect of personal hygiene. He succeeded in making the agency staff of his company a force for health promotion. Early in his insurance career, health officers and educators availed themselves of the opportunity to obtain the pamphlets and tracts prepared under his supervision for wide distribution among the general public and in the schools of the country.

Frankel advanced public health nursing possibly more than any other person of his generation. At the beginning of his work in the Metropolitan, he established a plan of coöperation with the visiting nursing organizations of the large cities of the country. Before very long, he had made satisfactory arrangements with these associations for nursing sick policy holders of his company over the entire area covered by its industrial business. In this way, the public health nursing movement of the country was substantially assisted and enabled to extend its operations in a manner that would have been thought impossible 25 years ago. It is also true that contact of the associations with the company resulted often in higher standards of bedside care, in the improvement of nursing records, in the establishment of a good accounting system, and in excellent supervision.

Frankel early established close contacts with health officers and others engaged in official health service, federal, state, and municipal. To all, he offered the coöperation of the company. Hundreds of campaigns were launched each year from his office to assist local health officers to popularize immunization against diphtheria, clean up the city, build tuberculosis sanatoriums, increase the municipal health budget, or check attacks on health service by those who were opposed to it.

His connection with the American Public Health Association began in 1909, when he became an active member. He was elected Treasurer in 1913, and his ambition was to build up the American Public Health Association until it became a leading force in public health work in America. He became President in 1919, and at once launched a campaign to increase the financial resources of the Association. He obtained large donations from sustaining members and directed a drive for a larger membership. Before his term of office was closed, the

Association had entered a period of expansion. The momentum of his activity carried it forward for 10 years until the membership and budget of the Association were more than doubled. His interest in the Association continued after his term of office expired and he watched its subsequent growth with pride. He was helpful in launching the Committee on Administrative Practice and in obtaining the first financial support which made the work of this committee possible. It was with much satisfaction that he saw its work extended from year to year until its activities included service to principal cities and states of the country.

Frankel was an extraordinary man in many ways. A gifted scientific investigator himself, he initiated and encouraged research in fundamental problems in the health field. He organized a number of demonstrations to discover how best to control tuberculosis and other communicable diseases. He developed a new public health literature. But probably the service by which he will be longest remembered is his demonstration that public health work, well conceived and administered, brings returns more than commensurate with its cost.

SHIBASABURO KITASATO, M.D.

THE death of Kitasato is of more than usual interest to bacteriologists and public health workers, in spite of the fact that for many years he has had very little touch with this country.

Born in 1856, he was sent by the Japanese Government to Germany in 1885, to study under Robert Koch, who at that time had reached the height of his fame, having announced his discovery of the bacillus of tuberculosis in 1882, and cholera in 1883.

Kitasato's fame will always rest upon his achievements in the isolation of the bacillus of tetanus in pure culture in 1889, his conjoint work with von Behring in which tetanus antitoxin was produced, which is held by many to have laid the foundation of modern serum therapy, and the discovery of the bacillus of bubonic plague in Hong Kong, in 1894. Yersin, during the same epidemic, isolated the germ independently.

In 1891, Kitasato returned to Japan, and a year later, established his private laboratory which was later subsidized by the government, and then taken over under the name of the Imperial Japanese Institution for Infectious Diseases. He created there a school of bacteriologists, among whom Shiga and Hata are especially well known.

A story is told in Germany that Kitasato was for a time very irregular in his attendance at the laboratory. One day Koch sent for

him, and told him that he would be returned to Japan promptly if he did not stick to his work. He disappeared for several days, and when he returned, brought with him a quantity of earth from which he isolated the germ of tetanus. For years afterwards, "Herr Kitasato's Tetanus Erde" was sold to students by the diener. A bottle of this earth is still among the mementos of the writer.

Kitasato was the recipient of many honors. In 1917, he was made a Member of the House of Peers by the Emperor of Japan, and in 1924, the title of Baron was conferred on him. He was a foreign member of the Royal Society of London.

WILLIAM CHARLES HASSLER, M.D.

IN the death, at the age of 63, of William Charles Hassler, City Health Officer of San Francisco, and President-elect of the American Public Health Association, the Association loses more than an officer and member of the Executive Board. He has been for many years a sincere, energetic worker for the interests of the Association. In 1920 he was our San Francisco host during the Annual Meeting. In 1930 he organized and was first president of the Western Branch, A. P. H. A., and increased the western membership more than four-fold in the past three years.

The extent of Dr. Hassler's administrative and public health ability has been too little appreciated outside San Francisco. Beginning his work with the Health Department shortly after his graduation from Cooper Medical College (now Stanford), in 1900, he was appointed Chief Sanitary Inspector of the City Health Department. He distinguished himself by establishing a registration office for births and deaths on the front porch of his residence on the first day of the 1906 earthquake and fire. Through his efforts and those of the U. S. Public Health Service in the enforcement of rat-proofing and inspection ordinances, bubonic plague, which occurred in 1906 and 1907, has never reappeared. He was appointed City Health Officer in 1915.

In 1918, his drastic enforcement of mask-wearing as an influenza control measure nearly cost his life by assassination. A bomb placed by a crank in his office failed to explode. In 1926 he was commissioned by the Surgeon General of the U. S. Public Health Service as a special representative at the Geneva Sanitary Conference. His continuity of policy for 31 years as a public officer has brought San Francisco unique advantages in the development of its health program.

Dr. Hassler became President-elect of the A. P. H. A. at the last Annual Meeting in Fort Worth, Tex. He would have assumed the presidency at the close of the Montreal meeting.

ASSOCIATION NEWS

SIXTIETH ANNUAL MEETING

AMERICAN PUBLIC HEALTH ASSOCIATION

Montreal—September 14-17

HEADQUARTERS—WINDSOR HOTEL

ENTERTAINMENT IN MONTREAL

THE Local Committee for the Montreal meeting makes the following preliminary announcement concerning entertainment for those who will attend:

On Monday evening, the opening day of the meeting, a dinner will be tendered to the Governing Council. This will provide an opportunity for the Governing Council to meet the representative body of Montreal citizens making up the Local Committee and representatives of the Federal, Provincial and Municipal Governments.

Following the general meeting on Monday evening, there will be dancing, and a buffet supper will be served.

An interesting event will be the garden

party which will be held on Mount Royal. At a spot known as Look-Out Point, the City has just completed a chalet which provides accommodation for a large number. Here afternoon tea will be served and a musical program will be given by the band of His Majesty's Grenadier Guards. From Look-Out Point, a panoramic view of the City is to be had. Beyond the City is seen the mighty St. Lawrence, and glimpses may be obtained of the Adirondack and the Green Mountain ranges. Transportation to Look-Out Point will be arranged.

The ladies will be invited to attend the Garden Party. A motor trip around the City has also been arranged for them.

SCIENTIFIC TRIPS

ARRANGEMENTS have been made for trips of general and scientific interest to various types of hospitals, large sewers under construction, filtration plants, incineration plants, milk pasteurization and industrial plants, the Radium Institute, and provincial and city health department laboratories.

The complete list of scientific trips will be published in the Entertainment Program, a copy of which each registrant will receive as well as the Final Program at the time of registration. Registration headquarters are located in Windsor Hall. The registration fee is \$2.00 for all delegates.

SPECIAL SESSION ON PUBLIC HEALTH ADMINISTRATION IN GREAT BRITAIN

THE following program has been arranged for Tuesday afternoon, September 15.

A Brief Review of British Public Health Administration. GEORGE F. BUCHAN, M.D., M.R.C.P., D.P.H., Medical Officer of Health, Willesden, London

Public Health and Public Assistance. SIR ALLAN POWELL, Public Assistance Officer, London County Council, London

The English Public Health Service—Education and Training. CHARLES PORTER, M.D., B.Sc., Medical Officer of Health, Marylebone, London

Maternal and Infant Services. JAMES FENTON, M.D., D.P.H., Medical Officer of Health, Kensington, London

NEW MEMBERS

Health Officers Section

- William R. Cameron, M.D., Hagerstown, Md.,
County Health Officer
Frank M. Fitch, M.D., Indianapolis, Ind.
(Assoc.)
Seth M. Kerron, M.D., Eugene, Ore., City and
County Health Officer
Frederick S. Leeder, M.D., Great Barrington,
Mass., Medical Director, Southern Berkshire
Health District
O. R. Taylor, M.D., Linden, Tex., Director,
Cass County Health Unit
Ralph Ten Have, M.D., Grand Haven, Mich.,
County Health Officer
William B. Terhune, M.D., Stockbridge, Mass.,
Chairman, Board of Health
Guy H. Turrell, M.D., Smithtown Branch,
L. I., N. Y., Health Officer

Laboratory Section

- Andrew Moldavan, M.Sc., Montreal, P. Que.,
Dairy Technician and Bacteriologist, Guar-
anteed Pure Milk Co., Ltd.
Edward J. Pugh, B.S., Wilkesbarre, Pa., Di-
rector, Kirby Health Center Laboratory

Vital Statistics Section

- Eleanor MacDonald, A.B., W. Somerville,
Mass., Statistician, State Dept. of Public
Health
Marguerite P. Potter, A.B., New York, N. Y.,
Statistician, Comm. on Neighborhood Health
Development

Public Health Engineering Section

- Martin E. Flentje, B.S., M.S., Harrisburg, Pa.,
Supt. Purification of Water Companies op-
erated by Community Water Service Co.
Onis M. Leonard, Frankfort, Ind., Director,
Dept. of Public Sanitation

Food, Drugs & Nutrition Section

- Helen Knowlton, M.A., Amherst, Mass., Asst.
Professor of Home Economics, State College
Enid E. Miner, Rock Springs, Wyo., Hospital
Dietitian, Wyoming General Hospital
A. Katheryn Royce, Burlington, Vt., Dietitian,
Mary Fletcher Hospital
Margaret R. Sandels, Ph.D., Tallahassee, Fla.,
Educator, Teaching and Investigations in
Nutrition, State College for Women
Eleanor F. Wells, B.S., M.A., Providence, R. I.,
Director, School of Homemaking, Y. W. C. A.

Child Hygiene Section

- C. Adele Brown, M.D., Oswego, N. Y., Medi-
cal Supervisor, City Schools
Dr. Mary A. Wilson, Newark, N. J. (Assoc.)

Public Health Education Section

- Harry S. Thomson, L.D.S., D.M.D., Toronto,
Ont., Field Secretary, Canadian Dental Hy-
giene Council

Public Health Nursing Section

- Anna L. Hartmann, R.N., Kirkwood, Mo., St.
Louis County Health Dept.
Marguerite K. Jacobsen, R.N., New York,
N. Y., Associate Director, Health Service,
Cleanliness Institute
Adele L. Kuhle, R.N., Clayton, Mo., Public
Health Nurse
Margaret Reddington, R.N., St. Joseph, Mo.,
County Public Health Nurse
Beatrice M. Sibley, B.S., Union City, N. J.,
Supv. of Nurses, Metropolitan Life Ins. Co.
Martha B. Waltmire, R.N., Perry, Fla., County
Health Nurse

Unaffiliated

- R. Gautier, M.D., Singapore, S. S., Director,
Health Organization, Eastern Bureau, League
of Nations (Assoc.)
Dr. R. Subramaniam, New York, N. Y., temp.,
Public Health Service, Madras, India (Assoc.)

DECEASED MEMBERS

- Dr. Eugene Lyman Fisk, New York, N. Y.,
Elected Member 1915, Fellow 1922
Lee K. Frankel, New York, N. Y., Elected
Member 1909, Fellow 1922
W. C. Hassler, M.D., San Francisco, Calif.,
Elected Member 1916, Fellow 1922
Wilson F. Monfort, St. Louis, Mo., Elected
Member 1908, Fellow 1922
Edward L. Creeden, M.D., New York, N. Y.,
Elected Member 1927
William S. Keister, M.D., Towson, Md., Elected
Member 1913
Thomas D. Maher, M.D., San Francisco, Calif.,
Elected Member 1929

APPLICANTS FOR FELLOWSHIP

- HEALTH OFFICERS' SECTION: Joseph W. Moun-
tin, M.D., Washington, D. C.
EPIDEMIOLOGY SECTION: Willard P. Greene,
M.D., Minneapolis, Minn., Clarence H. Kin-
nahan, M.D., Topeka, Kans.
VITAL STATISTICS SECTION: Sheldon L. Howard,
Springfield, Ill.
UNAFFILIATED: Emile Nadeau, M.D., Quebec,
Que., Alphonse Lessard, M.D., Quebec, Que.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Health Demonstration in New York City—The work of the Bellevue-Yorkville Health Demonstration in 1930 was concentrated largely in co-operating with the Department of Health in working out an effective plan of local health administration. Two special projects were undertaken. One thousand children of 13 and 14 years of age were examined for tuberculosis to ascertain the kind and amount of tuberculous infection in a cross-section of the child population. Each patient was given a physical examination, tuberculin test, and X-ray of the chest. An intensive educational program to acquaint the population with the dangers of the venereal diseases was also instituted.

During 1930 each nurse in the Yorkville District averaged a case load of 331 patients in 227 families, and was responsible for the health work in at least one school and averaged nearly 3 half-days a week in clinic work.

No death from diphtheria occurred in the district during 1930. In fact, there has not been a death since August, 1929, although 94 cases of diphtheria were reported in 1930. A house-to-house canvass by nurses disclosed the fact that in 253 families there were 502 children between the ages of 9 months and 10 years. Of these, 283 had been protected against diphtheria and 219 had not received such protection.—Bellevue-Yorkville Health Demonstration, Milbank Memorial Fund, 1930.

Typhoid Fever in Ohio River Cities—An epidemiological study has been made of the possible relationship to the public water supply of the resi-

due in typhoid fever cases in 6 Ohio River cities. Included in the study are East Liverpool, Steubenville, Wheeling, Ashland, Ironton, and Portsmouth. The Ohio River is the source of the public water supply of each city studied. While originally supplied with untreated water, at the time of the study all 6 supplies were treated by coagulation-sedimentation-filtration and disinfection with chlorine.

During the period of raw water consumption the typhoid fever incidence in each city was uniformly very high in every month of the year. Following the installation of treatment systems, the typhoid fever incidence fell to a low rate comparable to that enjoyed by cities with safe water supplies. Also the seasonal distribution changed so as to give a definite summer and fall incidence. An epidemiological study of reported cases during 1927 and 1928 failed to reveal any evidence that the public water supply was a factor in the transmission of typhoid fever.—M. V. Veldee, *An Epidemiological Study of Typhoid Fever in Six Ohio River Cities*, *Pub. Health Rep.*, 46, 1460 (June 19), 1931.

Eradication of Syphilis—Four persons per 1,000 of the population or nearly half a million persons in the United States are constantly under treatment on account of syphilis. In urban areas the rate is 5 times as high as in rural areas and there are half again as many cases among males as females.

Information furnished by practising physicians in New York State exclusive of New York City indicates that in 1930 there were 2,800 more cases of syphilis under treatment than in 1927.

The health officer, although interested in movements for social betterment, can most profitably restrict his activities to the application of effective well known medical and public health procedures. Briefly, the control of syphilis involves two elements: first, that every infected person must take treatment; and second, that facilities for diagnosis and treatment must be made freely available.

Legal aspects of the control problem involve case reporting, notification of sources of infection, compulsory treatment, and quarantine of irresponsible persons.

The medical service should include laboratory diagnostic facilities, adequate clinical services, free distribution of drugs, payment of physicians in rural areas for treating those unable to pay, and prophylaxis.

Among the epidemiological measures are: inquiry to determine source of infection, examination of contacts, and concentration of effort where necessary in early cases. Medical social service should be available to physicians as well as to clinics, to make family adjustments and to return lapsed cases for treatment. Educational measures should include the training of personnel, which includes the physicians, nurses, and social workers, education of the public and education of the patient.

The New York State program for the control of syphilis includes the establishment of a state-wide and state-aided system of county boards of health under the direction of trained, full-time health officers.—Thomas Parran, Jr., *The Eradication of Syphilis as a Public Health Objective*, *J. A. M. A.*, 97, 73 (July 11), 1931.

Rural Health Program—On February 6, 1931, Congress appropriated \$2,000,000.00 for the promotion of rural sanitation in drought stricken areas. The restrictions on this appropriation

are not like those imposed upon the Public Health Service in the administration of rural health work elsewhere than in the drought stricken region. It is not required that at least 50 per cent of the total cost of any project be defrayed from local sources. The appropriation is of an emergency character and terminates on June 30, 1932. Twenty-two states are considered as being included in the drought stricken areas.

An opportunity is presented to demonstrate the value of properly organized local health work. There is need for the further development in the Public Health Service of—(1) an adequate consultation and advisory service, (2) a service to develop better trained public health personnel, and (3) the extension of studies, surveys and experimental demonstrations with the view of obtaining additional knowledge with which to increase the effectiveness of public health administration generally, and produce more satisfactory results.—W. F. Draper, *Some Essential Considerations in Connection with the Rural Health Program*, *Pub. Health Rep.*, 46, 1617 (July 10), 1931.

Health Demonstration in China—With the financial aid of the Milbank Memorial Fund, there has been established in a rural county of North China with a population of 400,000 a demonstrational health unit. Ting Hsien is 85 per cent rural, the largest city containing 13,556 inhabitants, and there being 472 scattered villages. The health demonstration area includes the city and the neighboring 72 villages, a population of approximately 50,000.

Over 90 per cent of the people are illiterate. Most of them are poor, ignorant, and superstitious. The chief causes of controllable mortality are smallpox, gastrointestinal diseases, tetanus neonatorum, and tuberculosis. During the first year of the demonstra-

tion particular emphasis has been placed upon health education, improvement of the local water supplies, vaccination against smallpox, and the promotion of social hygiene.—Hsun-Yuan Yao, *The First Year of the Rural Health Experiment in Ting Hsien, China*, Milbank Memorial Fund, *Quart. Bull.*, July, 1931.

Diphtheria Prevention in Philadelphia—During the month of June for each of the past 4 years, the Health Department has carried on an intensive campaign to secure the protection of

preschool children against diphtheria. In June, 1931, there were 85 school clinics in addition to the 9 regular health centers at which this service was given free of charge to those who applied. In 1928 protection was given to 24,800 preschool children. In 1929 the number protected was 20,400, while each of the two years 1930 and 1931 protection was given to 21,000 preschool children. This work has resulted in a reduction in the incidence of diphtheria.—*Health-fax*, Philadelphia Department of Health, June 29, 1931.

LABORATORY

JOHN F. NORTON, PH. D.

A COMPACT APPARATUS FOR THE DETERMINATION OF CARBON MONOXIDE BY THE IODINE PENTOXIDE METHOD

MATHEW J. MARTINEK

Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

IN order to conserve working space, an improved and portable apparatus for determination of carbon monoxide in air by the iodine pentoxide method has been designed and perfected. It has all the salient features of our older and larger type,¹ and other features which give it an advantage over the former apparatus.

Figure I shows the construction of the apparatus. A framework, V-V, is attached to a base Y. The various absorption towers and other pieces of apparatus are arranged around this framework in series. The sample is introduced into the apparatus at either T or S, depending on whether it is to be collected by continuous flow or from a gas-sampling bottle. R is a three-way stopcock which controls these openings.

The sample passes from the inlet to the towers O and M, containing concentrated sulphuric acid, to remove most of the moisture; then to K, concentrated sulphuric acid heated to 150° C. by means of an oil bath, E, to absorb the heavy hydrocarbons, most of the gasoline, and the methane; then to C, cold concentrated sulphuric acid, to catch any of the fumes liberated from K; then to A, activated charcoal, which removes the last traces of unburned gasoline and hydrogen; next to B, soda lime, and to D, dehydrite, to remove carbon dioxide and the last traces of moisture. These absorption towers are connected to a hard glass U-tube, G, containing iodine pentoxide, immersed in the oil bath, E, kept constantly at 150° C. by means of a thermostat, I.

Figure 1.

and electric light, J, connected in series. U is a microfarad condenser attached to the circuit to prevent unnecessary sparking.

The liberated iodine is finally absorbed in a specially constructed absorption bulb, P, containing 5 c.c. of 10 per cent potassium iodide. This bulb is connected at Q, and fits into the bracket N. Trap L prevents any of the solution in P from being drawn back into the tube containing the iodine pentoxide. The outlet end of the bulb P is connected to a standard meter, which registers the volume of gas flowing through the apparatus. The heating of the oil bath is done by means of an electric stove, F.

In case electricity is not available, the heating may be done with an alcohol lamp or oil stove. Thermometer H

indicates the temperature of the bath. The gas is drawn through the apparatus by means of an electric pump, for which a water pump or a series of aspirating bottles can be substituted when electricity is not available.

The space occupied by the new apparatus is much less than that required by the older type. By attaching the wooden case, Z-Z, which is held in place by means of catch-locks, X-X, the apparatus is made portable and can be carried from place to place with the handle W. By its use accurate determinations of carbon monoxide in air can be made in the field.

QUANTITATIVE DETERMINATION OF ODOR IN WATER

CHARLES H. SPAULDING

Municipal Water Purification Plant, Springfield, Ill.

THE past five years have seen a wonderful response in the art of water purification to the public demand for water free from odor and taste. There are now a surprising variety of methods of recognized value in prevention and removal of tastes and odors, an excellent summary of which is contained in a paper by Paul Hansen, presented at the last convention of the A. W. W. A. Equally surprising is the fact that these methods have grown up without any yardstick by which to measure results or existing conditions.

It is not practical nor safe to determine taste indiscriminately on raw and partially purified waters, but fortunately most tastes are represented by odors. However, the determination of odor according to *Standard Methods* of the A. P. H. A. is not in any sense a quantitative determination, but merely the record of the opinion of the observer based on a momentary impression which cannot be recorded and referred to for comparison. While this method is the one which has been used generally, it must be obvious that it is not very useful in measuring the merits of odor removal processes—a problem of practical importance. Without a quantitative measure one can only guess at what to do and when to do it.

A method that does make possible a quantitative record of odor has been used by the author and others during the past few months. This is a determination of the threshold number which may be defined as the reciprocal of the highest dilution of the water which can be distinguished from odor-free water.

Example: 1 ml. of an unknown mixed with 99 ml. of odor-free water

can be distinguished from 100 ml. of odor-free water, while a higher dilution cannot; the odor or threshold number is 100. If a dilution of 25 to 100 is required to distinguish, the odor is 4, and so on.

ODOR-FREE WATER

Water free from odor is prepared by boiling distilled water. Usually we find the odor present in the distilled water is not entirely removed until 10 per cent or more has boiled away. The steam may be cautiously inhaled from time to time to note when removal of odor is complete. Cool to water temperature.

PROCEDURE

Make up a series of dilutions of the unknown to 100 ml. each, using odor-free water. Place in 500 ml. Erlenmeyer flasks previously marked. Cover flasks with well fitting watch glasses. The range of the dilutions will depend on the quantity of odor present. The highest dilution should contain less than the amount required to distinguish; while the lowest dilution will contain more than minimum amount required. Large steps of dilution will necessarily be employed until the proximate range is located. Finally, the steps should increase by increments of 20 per cent, as the method is of this accuracy or better.

A blank flask contains 100 ml. of odor-free water. Take one of the series of dilutions, shuffle with the blank and attempt to distinguish. The observation is made by shaking the flask vigorously for 1 or 2 seconds, lifting the watch glass and inhaling deeply from the mouth of the flask. If the unknown

can be identified, a higher dilution is tried, or *vice versa*.

To check an observation it is usually necessary to prepare a fresh dilution, since the vigorous shaking and aeration is likely to make a perceptible difference in the threshold odor when repeated.

The flasks used should be steamed out by boiling water before using. The hands should be clean and free from odors such as tobacco, soap, etc. The necks of the flasks should be immersed occasionally in boiling water.

Getting the proximate range of the odor may be tedious until experience is acquired. Several hours may be consumed before definite decisions can be made on a single sample. Results are obtained more rapidly by working from

lower dilutions to higher, as the intensity of odor in the lower dilution suggests the next higher step and seems to sensitize the observer to the test. Eventually, 10 to 15 minutes per sample will suffice for unknowns; while for plant samples in which the range can be predicted less time will be required. The method may be used for hot as well as cold odors. In the case of hot odors a temperature of 65° C. is about the limit of nasal tolerance.

We have not thus far noted any marked discrepancy in the results obtained by this method in the hands of trained, conscientious observers. There does seem to be considerable diffidence in the beginner resembling the first efforts of a child to walk, and the results may be somewhat erratic at the start.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Mortality by Age Groups in Wisconsin, 1930—Recent press notices, released by the Wisconsin State Board of Health, contain interesting information concerning the chief causes of death at certain age periods in that state during 1930.

For infants under 1 year of age, the chief cause of death was premature birth, which was responsible for nearly a third of the total deaths at this age. From ages 1 to 4, the highest mortality was caused by pneumonia; from 5 to 19, by accidents; from 20 to 39, by tuberculosis; and above the age of 40, by heart disease.

The important rôle played by accidents in the mortality record is shown by the fact that after the first year of life up to the age of 50, it was one of the three leading causes of death. Dur-

ing early childhood, ages 1 to 4, more deaths were attributed to this cause than to any one of the much feared childhood diseases of measles, diphtheria, scarlet fever or influenza. From 5 to 19, it was the outstanding cause of mortality, and during the period 20 to 39 it was exceeded only by tuberculosis. Even during the 40's and 50's, it was, next to heart disease and cancer, the chief cause of death.

Despite the great strides made during recent years in the reduction of tuberculosis, this disease caused more deaths between the ages of 20 and 40 in Wisconsin during 1930 than any other disease or condition. With the exception of accidents this disease was the leading cause of death, also during the age period 15-19. While the white plague may never regain the ascendancy it

once held in the general death rate, it is evident that, at least during this period of life, there is still room for much improvement.

Heart disease, as might be expected, was an important mortality factor throughout the life span. After 40, it was the chief cause of death, while in each earlier age group it was well up among the six leading causes.

Another disease which predominated throughout the entire span of life was pneumonia. At no age did it hold a position in the frequency scale lower than sixth and, as previously stated, during early childhood it was the most important cause of death.

That cancer, as a cause of death, should be exceeded only by heart disease in the late years of life was, of course, to be expected. But it will surprise many to find this disease among the ten leading causes of death during adolescence and early maturity.

The full significance of the figures pertaining to puerperal mortality in Wisconsin is not brought out by this study, since they relate to the total population instead of to females alone. If this distinction had been made, this group of causes would have figured even more prominently as a cause of death than now appears. As it is, some idea of the importance of puerperal conditions among the leading causes of death in Wisconsin may be derived from the fact that they averaged about fourth in rank throughout the ages 15 to 34. In the absence of specific figures, it is probable that among women within this age period, more lives are lost as a result of conditions accompanying childbirth than from any other cause, excepting tuberculosis and possibly accidents.

Other causes that merit attention are appendicitis and suicides. The former was one of the chief causes of mortality from the age of 3 to age 50. It ranked particularly high during childhood. At ages 5-14, it was exceeded only by acci-

dents, and at age 3-4, by pneumonia, diarrhea and enteritis, and accidents in the order named. Suicide remained continuously among the chief causes of death from age 20 to 69, maintaining an average rank of about seventh throughout this period.

The results of this study point to the practical advantage that might be derived from an analysis along these lines of similar material covering a more extensive territory such as the United States Registration Area.

Mortality Statistics for France—The Service de la statistique generale de la France has published a volume of general statistics for 1928, from which were made several excerpts for the *Siècle medical*. Of the 674,046 deaths recorded in France in 1928, 344,999 were of males and 329,047 were of females.

The mortality rate is thus 16.6 per 1,000 of population, or 17.6 for males and 15.7 for females. It is evident, therefore, that the mortality rate for males is higher than for females, as is nearly always the case. The excess amounts to 19 per 10,000, or to 12.1 per cent—a wide difference, and yet not so great as the differences that appear on analysis of the deaths and classification according to age groups. For instance, in the 10 to 24 age groups the number of deaths of females is greater than that of males, and particularly in the 15 to 19 groups, a result that may be attributed in part to childbirth and in part to the reduced resistance brought about in woman by the onset of puberty. But from age 24 on, the tide turns the other way, and in the 45 to 59 year age groups the mortality of men is about 50 per cent higher than that of women.

One condition which prevents drawing from the official statistics all the conclusions that would have value from the standpoint of public health is the large number of deaths recorded as

"cause unknown." Such statements are found more frequently in the large cities than in the rural districts, which is something of a reflection on the acumen of city practitioners.

In Dijon 635 deaths out of 1,000 are recorded by practitioners with the statement "cause unknown"; in Marseilles there are 599 out of 1,000, and in Grenoble 159 out of 1,000; whereas in the departments in which these cities are located the proportion, exclusive of these cities, ranges from 4.95 to 105.

It is possible that in some instances the rural practitioners pretend to have established a more precise diagnosis than is justified by the facts, and that the physicians of the large cities are more modest in their statements. It is to be considered also that necropsies, the only guarantee of a precise diagnosis, are seldom performed in the rural districts, whereas they are much more frequent in the large cities, where there are hospitals. It is, however, gratifying to note that the number of deaths from unknown causes is decreasing from year to year.

In the department of the Seine, the statistics show only 18 deaths per 1,000 as due to "unknown causes," as against 61 in 1925. But the proportion is still 569 in the department of Landes, in southwestern France, and appears to correspond to the greater or less perfection in the organization of the medical service.—*J. A. M. A.*, 97: 114 (July 11), 1931.

Trends in Population Increase and Distribution Among States During 1920-1930—The 1930 U. S. Census shows an increase of 17,064,426 persons during the past decade as compared with 13,738,354 during 1910-1920, while the respective rates of growth appear as 16.1 per cent and 14.9 per cent. If allowance is made for the change in the dates of enumeration, April 15, 1910, January 1, 1920, and April 1,

1930, and if a period of exactly 10 years is used, the 1920-1930 increase becomes 16,648,000, or 15.7 per cent; and the 1910-1920 increase 14,151,000, or 15.4 per cent. On this basis the rate of growth for the decade just past is only very slightly in excess of that of the preceding one. Both of these rates are well under that of the 21.0 per cent for the 1900-1910 period.

Comparing 1930 with 1920 there was a decline of nearly 16 per cent in the number of births, and of 31 per cent in the excess of births over deaths. The number of deaths has been fairly steady since 1920, although showing a slight increase as the population has grown. Net immigration varied widely from 1920 to 1923, but under the quota system since 1924, it has been fairly stable, though declining slightly. The excess of births over deaths has been much more important than net immigration in contributing to population growth, for only in 1920 and 1923 did less than four-fifths of the gain come from natural increase.

In 1930, the excess of births over deaths was over 11 times as important as net immigration in contributing to population growth. Although the largest excess of births over deaths occurred in 1921, the largest gain in population occurred in 1923, due to heavy immigration. The gain in population in 1930 was only 56 per cent of that in 1921 and 52 per cent of that in 1923. With only 1,110,000 persons added to the population during 1930, and with each year since 1923 showing a smaller increase than its predecessor, it is almost certain that the 1930-1940 gain will be less than 12,000,000, and quite likely that it will be as low as 9,000,000. This would mean a rate of growth of from 7.5 per cent to 10 per cent and a 1940 population of between 132,000,000 and 135,000,000.

California and Florida had the largest rates of increase in population be-

tween 1920 and 1930 with Michigan, Arizona, New Jersey, Texas, North Carolina, Oregon and New York all gaining over 20 per cent. Of these states, New Jersey, New York, California, and Michigan are primarily industrial and commercial; North Carolina and Texas have been experiencing a rather rapid industrial development and urban growth. Possibly the rapid increase of New York is the most surprising of these states. About three-fifths of its growth took place in New York City, which might have been expected to grow considerably less rapidly because of its size and population density. Probably the same factors that brought about this rapid growth in New York City were responsible for so much of the gain in New Jersey occurring in the northeastern part of the state, and for Connecticut being the only one of the New England states to grow as rapidly as the nation as a whole. States whose rate of growth was under 10 per cent during the decade just ended include Maine, New Hampshire, and Vermont; all of the West North Central states; and Delaware, Virginia, South Carolina, Georgia, Kentucky, Arkansas, Montana and Idaho. Barring Delaware, these are either New England states or states in which agriculture is the important occupation.

The greatest shifts in rate of growth during 1920-1930 as compared with the preceding decade were the declines that occurred in the Mountain states. Although New Mexico and Nevada grew faster than in 1910-1920, the rate for the division as a whole was cut from 26.7 to 11.0 per cent. In the balance of the country, the larger declines (i.e., amounting to one-fourth or more) occurred in Massachusetts, Connecticut, Ohio, Minnesota, Iowa, North Dakota, Nebraska, Delaware, Virginia, South Carolina, Georgia, and Arkansas. Barring Ohio and Delaware, the statement made above regarding states with a rate

of growth of less than 10 per cent may be repeated for states whose rate of growth declined decidedly; namely, they are either New England states, or agricultural states.

The rural rate of increase of 8.8 per cent during 1920-1930 is slightly larger than that of 6.8 per cent for 1910-1920, while the urban rate of 23.1 per cent is slightly less than that of 24.5 per cent for the earlier decade. According to statements made regarding the economic situation of agriculture and urban industries, it would be expected that the situation would be reversed, that the rural rate of increase should have been lower in 1920-1930 than in the previous decade and the urban rate higher. A considerable part of the rural increase in recent years is due to the development of "acre-lot colonies" along the roads near cities and towns and has no connection with agriculture. Thus, the rural population in Massachusetts, Connecticut, New York, New Jersey and Pennsylvania increased 1,085,345 from 1920 to 1930, by far the greater part being due to city workers seeking country homes.

On the other hand, Indiana, Illinois, Wisconsin and the 7 West North Central states (which comprise about the best of our farming area) had a gain in rural population of only 70,452, Iowa and Missouri even losing 48,549 persons from rural communities. In the remaining states the situation is not so clean-cut.

The rural increase of 648,801 in California, the largest of any state, is probably more suburban than agricultural. In Texas, North Carolina, and Oklahoma, where the gain in rural population totaled 943,429, the greater part undoubtedly was agricultural, due to the expansion of cotton farming into areas relatively free from the boll weevil. On the whole, however, it is evident that "acre-lot colonies" contributed a large share, certainly two-fifths and probably

over one-half, to the rural growth, and that without this new development, the 1920-1930 rate of rural gain would have been still farther under the urban rate for this decade, and well below the rural rate for 1910-1920.—P. K. Whelpton, *Population Trends in Population Increase and Distribution during 1920-1930*, *Am. J. Sociol.*, 36: 865-879 (May), 1931.

Ten Years of Legalized Abortion in Soviet Union—On the tenth anniversary of the existence of legalized abortion in Russia (Nov. 20, 1930), Boyko makes an extensive survey of it. Russia is the only country in the world in which abortion is legalized and every woman has there the right to request that it should be performed if there are present any indications of a social character.

The author recalls the situation in Russia in the prerevolutionary days. The well-to-do classes got the best specialists and the poor people were left to the mercy of ignorant midwives or were left alone entirely without any help whatever. They paid heavily for it, mostly by their lives or by various chronic ailments which developed after unattended labors.

The aim of all Russian health departments throughout the country now is to take away the initiative from the criminal abortionists and shift it to the legal channels for a modern hospital. In spite of legalization, for the years 1922, 1923 and 1924 there were recorded in Russia 3,000 deaths from criminal abortion in the small villages of the republic of Russia proper (not of the whole union). The author stresses that these figures are far from complete.

The law requires that to every woman who applies for an abortion must be explained the risk of it to her life and future health. There is outlined a defi-

nite plan of indications of a social nature for abortion, and the government opened all over the country many so-called abortaries, most of them free. Abortion in Russia is at present accessible to every woman.

The following legal changes have been introduced lately: (1) The time limit is 3 months. If there is any medical indication, no limit in time is necessary. (2) Repeated abortions are not allowed until 6 months has elapsed since the last pregnancy. (3) The patient has to stay in bed for 3 days. (4) The attending physician has the right to refuse to perform an abortion and he has to refuse it when he finds a contraindication from the medical side.

The legislation on abortion in Russia met a flood of criticism, especially abroad. The claim was that such a law would lead to the degeneration of the nation. The author disproves this assertion, stating that it has no ground whatever. He shows that the birth rate in Russia for each 1,000 of population was: in 1911 (prerevolutionary), 43.8; 1923 (after the revolution), 42.2; 1924, 42.9; 1925, 44.2; and 1926, 43.2. In 1929 the net increase in population of Russia was 23 for each 1,000, while in France it was 1.3, and in England, 3.4. The total increase in population is at present $3\frac{1}{2}$ million yearly.

The motives on which abortion is asked for in Russia were as follows: poor economic conditions, 48 per cent; desire to hide pregnancy, in large towns, 0.5 per cent; in country places, 4.1 per cent; various sicknesses, 21.6 per cent; the presence of a nursling in the family, 6.8 per cent; desire not to have a child, around 10 per cent. Legalized abortion is the only means for women's emancipation because there are not yet any contraceptives that prevent pregnancy with certainty.—*J. A. M. A.*, 97: 218 (July 18), 1931.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

SANITARY ENGINEERING IN A COUNTY HEALTH DEPARTMENT *

R. E. COOK

Sanitary Engineer, Suffolk County Health Department, Riverhead, N. Y.

SUFFOLK County occupies the eastern two-thirds of Long Island and has an area of about 920 square miles. It is 90 miles long and varies in width from 12 to 20 miles. It is a county of small communities, having 48 with a population of 1,000 or more, the largest with only 11,000. The total population of the county is about 160,000 but this is greatly increased in summer by the thousands of people who enjoy the recreational advantages of the seashore. Moreover, the permanent population showed an increase in the last decade of 50 per cent, which is much larger than in the preceding 10 years.

Suffolk County consists of 10 townships and 28 incorporated villages, making 38 separate health districts before the establishment of the County Health Department. These 10 towns vary in population from 1,000 to 30,000 people and in size from one of the smallest towns in the state to the largest, which is almost as large as the combined area of the three counties which constitute the remaining one-third of the Island. Moreover, only 11 of the 48 communities mentioned are incorporated. These communities have spread beyond their boundaries so that in the largest community about one-third of the popula-

tion lives outside the incorporated limits.

With such rapid growth and overlapping of town and village jurisdictions, a county health department with adequate power and a full-time personnel was distinctly needed, and one was organized in November, 1928. It was the second in New York State and the first organized entirely by the people of the county.

With its organization the local boards of health, except in the 7 villages having a population of over 3,000, were abolished and the boards of health and health officers in these 7 villages were placed under the supervision of the County Board of Health, which immediately fell heir to all the sanitary problems in the county. The department as organized consists of a Board of Health of 7 members, a commissioner, deputy commissioner, sanitary engineer, veterinarian, two milk and dairy inspectors, bacteriologist, two clerks, several nurses and part-time assistant deputies.

The duties of the sanitary engineer in a county health department, or of the county sanitary engineer, may be divided into two broad divisions—that of assisting the Engineering Division of the State Health Department in the protection and supervision of the public water supplies and of the installation and operation of sewer systems and sewage disposal plants, and as agent of the local board of health in dealing with

* Abstract of paper presented before the New York State Sewage Works Association at Freeport, L. I., N. Y., June 5, 1931.

local problems in sanitation as herein-after discussed.

The county sanitary engineer supplements the work of the state on one hand, and acts as consulting engineer to the town and village authorities on the other. In no way, however, does he interfere with the professional consulting engineer, but on the contrary does a great deal to stimulate the engaging of competent sanitary engineers by local authorities in order properly to carry out his recommendations.

The promotion of sanitation in communities is a very important duty and one that is difficult to evaluate, as it is chiefly accomplished by personal contacts and conferences with the authorities and civic organizations in these communities.

WATER SUPPLY

The chief and most important duty of the state and county sanitary engineers is the protection and supervision of the public water supplies. In New York State the State Health Department has full authority over the sanitary conditions of public water supplies, but as there are over 600 of these, it is difficult for the State Health Department to maintain continual careful supervision over all. It therefore devolves upon the local health department, in this case the county sanitary engineer, to maintain such close supervision and to do the necessary field work. He is greatly aided in this work by the existence of a laboratory in the County Health Department with a competent bacteriologist in charge.

In Suffolk County there are 31 public water supplies, 2 of which were recently discovered. These range in size from one serving about 100 to one serving about 50,000 people. Of the 48 communities having a population of over 1,000; all but seven, or 72 per cent of the population, are served with public supplies and these 7 communities will

soon have public supplies. All these supplies except 2 are derived from wells, chiefly shallow wells, as Long Island is underlain with an extensive and practically pure ground water supply which is cheaply and easily obtainable. This fact somewhat prevents the extension of public water systems in the smaller communities, as it is comparatively easy for the home owner in a sparsely settled village to drive a small shallow well and derive fairly pure water at small cost.

During the last year samples of water have been collected from all water supplies once a month and a sanitary inspection of each supply is made at the same time. The rapid growth of population, and the consequent construction of many new houses, necessitates a careful watch by the county sanitary engineer on the sources of supply in order to prevent the location of any cesspool or other source of pollution near the supply. In some cases, the engineer supervises the installation of proper individual disposal plants placed beyond the required minimum distance from the wells. In other places he has helped to eliminate sources of possible pollution. In some instances where the presence of organisms of the *B. coli* group had been indicated, the seeming contamination was due to defects in the system and was soon cleared up.

The 7 chlorination plants in the county are inspected semimonthly, residual tests for chlorine are made, advice to the operator on the operation of the chlorinator is given and a check-up is made on the report furnished by the operator to the State Health Department. The maintenance of a residual of chlorine of at least 0.1 p.p.m. has been rigidly adhered to. Except for the 2 surface water supplies, the chlorine demand of the waters in Suffolk County is extremely low and careful control over chlorination must be maintained in order to prevent tastes due to over dosages.

The county sanitary engineer is frequently called upon to inspect and report upon the sanitary condition of many private water supplies. In the first year of the laboratory, 47 of these supplies were examined. Including public supplies, the total number of samples collected by the sanitary engineer during that year was 200.

He is also called upon to assist communities in the securing of more palatable water supplies, a service not necessarily of a sanitary nature, but yet somewhat affecting public health because if the taste of a public supply is unpleasant, the people will complain to the Health Department and tend to drive their own wells, which, in the built-up sections, will be more or less contaminated.

In particular, a certain village had a water supply which was high in salt content, high in iron, carbon dioxide and with a low pH. Under the recommendation of the county sanitary engineer, a new piece of property was secured and a test well driven. The results of analyses of samples collected from this well showed it to be satisfactory from all standpoints, and accordingly it was recommended that the village install a new system but particularly to locate the wells as far apart as possible and never to pump them over the rate used on the test well. These recommendations were fully carried out only after considerable time and patience had been expended to convince the village authorities.

In the two years in which the county has had a sanitary engineer, 4 new sources of water supply have been approved and the sources of pollution have been entirely removed from 3 supplies which had been threatened with potential pollution for many years.

SEWERAGE AND SEWAGE DISPOSAL

The satisfactory disposal of sewage on a broad scale in the communities in

Suffolk County, particularly in the western part, is the big sanitary problem and the most difficult one to solve properly. When numerous complaints are received from nuisances caused by insanitary conditions due to overflowing cesspools or the discharge of raw sewage into creeks and bays, it is the duty of the county sanitary engineer to agitate and stimulate the construction of a proper sanitary sewer system and disposal plant. Where the State Health Department has already made a sanitary survey recommending sewers, he endeavors to have these sewers installed by developing a plan and a tentative estimate of cost. The difficulty of promoting sewer systems on Long Island, particularly in Suffolk County, is manifold for the following reasons:

1. The comparative ease of disposal of sewage into the generally prevalent sandy and gravelly soil by means of individual plants on small lots makes the great bulk of the population not in favor of them.

2. The flatness of the land and the high level of the ground water, especially on the south side of the island, makes the construction of sewers expensive.

3. The necessity for the protection of shell-fish bearing areas and bathing beaches, which are usually in shallow and not well circulated waters, makes the cost of treatment high.

4. The lack of incorporation of practically all the large villages makes the legal method difficult.

5. The rapid growth of the communities in the western part of the county and the consequent expenditure of public money for other necessary improvements make the growing communities reluctant to spend a large amount of money from which only the business and comparatively small built-up areas will receive especial benefit at that time.

The above reasons explain partly the fact that out of the 48 communities above mentioned, only 7 have sewer systems and 1 of the 7 has an adequate and comprehensive sewer system and disposal plant. However, 1 community is now constructing a system and another has been ordered by the State Health Department to construct one.

The county sanitary engineer has completed thorough reports on proposed sewer systems and disposal plants for 2 communities. With the publication of these reports, he will endeavor to seek their adoption and completion by continual personal work with the local committees, organizations and authorities.

The supervision of operation of existing sewage treatment plants is a very important duty of the county sanitary engineer because only 1 of the 7 plants above mentioned has a full-time, trained operator. The operators of the other 6 plants are only part-time and have varied occupations. They had to be convinced of the necessity for the regular report on operation which could be submitted to the State Department. It is almost physically impossible in 3 of these plants to make the regular orthotolodine residual test so the chlorine rate in these plants is fixed according to the maximum flow of sewage. However, all these plants excepting 1 make regular reports to the state and maintain fairly constant chlorine control.

There are numerous places, particularly in the western part of the county, where sewers are needed and it is to be hoped that a broad and comprehensive plan on an economical and logical basis can be worked out and established. With its establishment, it will be the duty of the county sanitary engineer to see that all the installations of sewers and sewage treatment plants are developed and installed according to that plan.

GARBAGE AND REFUSE DISPOSAL

The supervision of garbage and refuse disposal rests to some extent in the Board of Health. Garbage and other organic matter in the process of decay cause disagreeable odors and breed flies and rats. Also, such material is liable to catch fire and sometimes does, which produces smoke which has an obnoxious

odor. The indiscriminate dumping of garbage, together with the presence of many public dumps, causes nuisances detrimental to the health of considerable numbers of people in the vicinity of the congested and built-up areas.

The local health department receives many complaints concerning this improper garbage disposal. Where numerous complaints are received in one vicinity, the county sanitary engineer makes a thorough investigation noting the location of dumps and dumping areas and their proximity to houses and built-up sections and the existing facilities in that area for the collection and disposal of garbage and refuse. He then recommends the most logical, economical and sanitary method for collection and disposal. Investigations have already been made concerning the garbage and refuse situation affecting about one-half the people in the county and certain definite results accomplished.

The proper method for each locality differs, but the main point is at first to recommend a place and method of disposal and then build up the collection systems around this focal point. According to present-day practice, the most sanitary and economical method of destroying garbage and refuse is by means of a properly designed and operated incinerating plant.

Because of the conflicting political subdivisions on Long Island it was necessary (in the four chief investigations made by the County Health Department) to recommend different operating procedures to accomplish efficient waste collection and disposal. In one case the *township* was advised to establish an incinerator, in another, a combined incinerator and garbage collection *district* was formed, and in the other two cases, the construction of incinerators was recommended to the incorporated *villages*.

With the providing of incinerators in areas in the county, the towns and vil-

lages are prevailed upon to pass strict ordinances making it criminal to deposit any refuse and garbage in any places other than those provided, and in this way it is to be hoped that the county will be rid of this nuisance producing garbage and refuse dumping.

The County Health Department has already accomplished very definite results in the four chief investigations made. Two places have already spent \$110,000, another town has engaged an engineer and will spend about \$60,000, and in the fourth, the erection of a suitable incinerating plant is being favorably agitated by the inhabitants. In still other areas, the department will help to stimulate further action in order to provide as soon as possible the proper central incinerating plants for the disposal of all garbage and refuse.

NUISANCES

The investigation and abatement of nuisances is a function of the local health department and one that unfortunately at times consumes a considerable amount of the time of the engineer and the officials of the department. In Suffolk County, all complaints regarding alleged nuisances made to the Health Department are immediately investigated, largely by the county sanitary engineer.

The existence of a nuisance detrimental to health is largely a question of fact and it devolves upon the one who investigates it to decide whether a health nuisance exists or not. Many complainants are satisfied with a personal visit of an investigator because a large number of complaints are only disputes and do not come under the jurisdiction of the Health Department.

Where the department receives numerous complaints from one community relative to improper garbage or sewage disposal, the procedure is usually as mentioned above, that is, a thorough investigation of the whole

community's needs is made along these lines. Where isolated cases of these two conditions or similar conditions which might affect health are found, the engineer visits the place and in practically all cases secures voluntary compliance without recourse to legal action. In this way, a great number of major health nuisances, some of which have long existed, have been cleaned up by the County Health Department. In the second year of this department, 74 nuisances and complaints were investigated, 63 of which were entirely abated.

STREAM POLLUTION

The elimination and prevention of stream pollution is a subject which has recently engaged the attention of the Health Department in one particular instance. In this case, the river is a tidal stream, and it was a large shell-fish bearing area. A year ago this area was condemned by the Bureau of Marine Fisheries for the taking of shell-fish because of high bacterial counts and the apparent presence of human contamination. At the request of the town board of the town in which this river is located, a survey was made by the county sanitary engineer. The result of the survey showed the chief points of pollution to be near the head of the river where there were a group of houses, restaurants, and a hotel, and near the mouth of the river where there was a large state institution having an overloaded sewage plant and a large storm drain, the contents of which showed heavy pollution.

The County Health Department secured the voluntary elimination of the sources of pollution from the storm drain and also was able, by letter of recommendation, to have a new chlorinator installed at the sewage plant and the old one placed in proper operating condition. It was able, through the same procedure, to have the residents along the river remove their sources of

pollution and install proper sanitary disposal plants at a sufficient distance from the river. A thorough re-survey of this stream has been recently made by the department and it was found that the results of bacterial analyses had decidedly improved.

MILK SANITATION

The supervision of installation and operation of milk pasteurizing plants is placed under the direction of the sanitary engineer. In Suffolk County there are 2 dairy and milk inspectors whose function it is to supervise the dairies, of which there are between 200 and 300 producing milk sold in this county. The number of pasteurizing plants has been doubled in the county in the last 3 years so that there are now 12. Continual checking up on the recommendations made by the State Health Department concerning these plants resulted in the final approval of the plants existing at the time of the formation of the County Health Department.

The installation of the new plants was carefully watched by the county sanitary engineer in order that they would entirely fulfil the 75 provisions of the *State Sanitary Code* relating to construction, apparatus and sanitation because it is felt that the placing of a pasteurized milk cap on a bottle means to the milkman an insurance and to the public assurance that the milk contained therein is especially safe and a definite safeguard against the transference of any disease.

CAMPS

The County Health Department through its engineer enforces the provisions of the *State Sanitary Code* relating to camps, including the supervision of water supplies, milk supplies, disposal of garbage and sewage, and elimination of insects, particularly flies, and the issuing of the annual permit. In a survey made last summer there

were found about 50 camps in the county many of which had never been inspected before the formation of the County Health Department.

The installation of an adequate water supply under pressure and a water-carriage sewer system with a small sewage treatment plant has greatly helped in the prevention of water-borne diseases and in making the camp a healthful place. The chief difficulty found in sanitation is the proper collection and disposal of garbage and kitchen wastes with a consequent fly problem. The best way to prevent flies, it was explained to the camp directors, was not to allow the exposure of any garbage or other organic matter; in other words, all garbage should immediately be put into properly covered metal cans.

Various methods of disposal of garbage were in use. Some camps had it removed by farmers; some tried burning it; others had it buried; while others were so situated that the garbage was removed by a public collection system, which method is, of course, the best. With the exception of the latter method, burying under at least 6 inches of dirt each day seemed to be the simplest and best method and it was recommended in most places. Keeping the kitchen and its surroundings clean and free of any exposed organic matter was found to be the most satisfactory method of preventing or eliminating flies.

Of the 50 camps, only 33 were given permits last year and some of these only after repeated visits to clean up certain insanitary conditions. It was estimated that about 12,000 people were in the camps in Suffolk County during the summer of 1930.

SWIMMING POOLS

The *State Sanitary Code* prescribes regulations for the construction and operation of artificial and partly artificial swimming pools which regulations are to be enforced by the local health de-

partment. A survey made last year by the county sanitary engineer indicated that such pools in Suffolk County were open to the air and operated only during the summer months. Only 6 pools were found, all located on the south shore, adjacent to public bathing places and operated on the draw and fill method.

These pools were carefully inspected, visits being made on hot Sundays when the bathing was at its maximum peak. As no purification or disinfection process was being used, particular emphasis was laid on the bacterial quality of the water. The sources of supply of the water were carefully examined, and all except one were found to be satisfactory. The results of analyses of samples collected from the pools, with the exception of the last mentioned, showed a bacterial quality above the standard re-

quired by the *Code*. This last pool was slightly below the standard, due undoubtedly to the somewhat unsatisfactory source of the water. A special effort will be made before this pool opens this year to have the quality of the water improved either by disinfection or changing the source to wells or some other satisfactory method. A special permit or license is required for the operation of these pools.

In concluding this subject, it might be added that the particular problems mentioned would be somewhat different in other counties, but it is the duty of the county sanitary engineer, trained in the broad principles of sanitation laid down by the State Health Department, to apply these principles toward the solving of the particular problems in his jurisdiction.

DISCUSSION

JAMES L. BARRON

*Director, Division of Sanitation, Westchester County Department
of Health, White Plains, N. Y.*

MR. COOK'S paper presents an excellent review of the manifold functions of the sanitary engineer in a county health department. Through the engineer, and the inspectors working under his direction, many important contacts are made and services rendered to the individuals composing the population of the health district. Engineers of a state health department deal largely with municipalities and confine their activities primarily to the major problems of the water supply and the disposal of wastes. The county sanitary engineer has intimate contact with the officials of the municipalities or other governmental units within his territory and in addition renders service to smaller groups, organizations, institutions, and individ-

ual householders in numerous matters.

The sanitary engineer finds frequent opportunity to act as mediator and arbitrator between local municipalities or areas, and between various departments of the local government, where jealousies and suspicious attitudes or misunderstandings must be reconciled in order to promote a public good. There are many occasions when the differences of communities or groups of individuals with regard to matters of sanitation or conditions of environment need sympathetic and rational handling by the engineer. Such differences frequently arise over the disposition of garbage and the discharge of sewage.

Supervision of milk supplies can only be effective when all of its details are

centralized at one office. Adequate records of all sources and channels of delivery must be maintained. Inspections of dairies, shipping stations, pasteurizing and bottling plants, must be coordinated with the collection of samples and the interpretation and use of the results in the enforcement of the milk code. This work is a most important function of the sanitary engineer and it may well include the direction of a campaign for the eradication of bovine tuberculosis within the health district.

The New York *State Sanitary Code* imposes upon health officers the responsibility of issuing permits for the construction and operation of swimming pools. This is essentially an engineering job and in Westchester County where there are over 40 pools under the supervision of the County Health Department, valuable service has been rendered to the pool owners and operators in showing them how to run filters, apply chemicals, and make operating tests. In Westchester County it has been found necessary to require reports of daily operation on all swimming pools and these reports serve as the basis of the Health Officer's assurance that such pools are safe to use.

The multitude of complaints of nuisances, actual and alleged, which come to a county health department give the sanitary engineer many opportunities to exercise engineering judgment and to assist individuals in the solution of sani-

tary problems where the services of an engineer would not otherwise be obtainable. To the average householder a polluted well or a faulty private sewage disposal system presents a difficult problem, which, however, may in many cases be corrected by following recommendations of the sanitary engineer.

The health department is, in many cases, believed to have extraordinary police authority and to be capable of dealing with conditions which have no relation to public health. It has been found advisable in Westchester County to adopt a sanitary code, prepared by the engineer, which supplements the *State Sanitary Code* in many matters relating to general sanitation, foods, milk, and swimming pools. This code establishes penalties for violations, and serves to define the matters with which the health authority may deal. Experience thus far indicates that such a code is an invaluable instrument in the effective functioning of the sanitary engineer and his inspectors.

Sanitary engineering service is one of the most important to be rendered by a county health department. Obviously such service, together with many others from such a department, can be obtained only when health units are organized on the basis of a large population and taxable wealth sufficient to support trained personnel capable of administering the many phases of modern public health work.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., PH. D., AND LEONARD GREENBURG,
M. D., PH. D.

Eugene Lyman Fisk—The sudden death of a pioneer organizer of the Section on Industrial Hygiene in the Association has taken place. Dr. Eugene Lyman Fisk was one of the group at the Jacksonville Meeting in 1914 which formed the Section, and always took an active part in its work, having held all of the offices in the Section, and was Chairman at the Chicago Meeting in 1928.

A man, small in stature, quick in action and response, he will always be remembered for his business-like demeanor at our proceedings, his mental acuity and sly sense of humor, and innate good fellowship. We recall, at the height of a warm discussion before the Section at the Chicago Meeting, Dr. Fisk's apt question, "Gentlemen, are you discussing a condition of fact or a state of mind?" Similarly, all will recall his firm position on fundamentals, his spirit of congeniality and great fairness, and his labors with our various committees in which he spared neither time nor expense, while the finish he gave his reports was classical.

He was visiting his daughter who lives in Paris and had gone to Dresden to view the exhibit which the Life Extension Institute had loaned to the famous Hygienic Museum in that city when he was suddenly stricken, July 5. He was in his 65th year. As the world's great pioneer advocate of periodic medical examinations and their effectiveness in prolonging health and life, he unfortunately, as is so often the case with a pioneer leader, passed too soon out of the picture. Yet Professor Irving

Fisher comments that Dr. Fisk had lived longer than most of his family,

EUGENE LYMAN FISK, M.D.

which was a short-lived one, and attributes the real cause of his death to grief over the death of his wife.

One of the last pieces of work Dr. Fisk did while he was in France was the preparation in his own handwriting of the draft of his report as Chairman of our Committee on Industrial Fatigue, which he had hoped to work over and present in person at the Montreal Meeting in September. He was feeling quite himself when he made the trip from Paris to Dresden, so writes his secretary.

None need to be reminded that Dr. Fisk was the author, with Professor Irving Fisher, of the famous textbook, *How To Live*, 18 editions and numerous reprintings of which have appeared since 1915, or shortly after Dr. Fisk became the energetic Medical Director of the Life Extension Institute, in which the Hon. William Howard Taft was intimately interested and permitted his name to be used as Honorary President. The motif of this work is found in the following, which mottoes the 18th edition:

"Self love, my liege, is not so vile a sin, as self-neglecting.—*King Henry V, Act 2, Scene 4.*"

More closely bound up with the activities of our Association are to be mentioned his work on "Health Building and Life Extension," while his work in connection with the Council on National Defense laid the foundation for his books *Alcohol: Its Relation to Human Efficiency and Longevity*, and *Health for the Soldier and Sailor* (with Prof. Fisher), to which is to be added *Food: Fuel for the Human Engine*. To the medical world, particularly insurance examiners, his work with Dr. J. Ramser Crawford, *How to Make the Periodic Health Examination*, is the acknowledged leader in its field.

Naturally Dr. Fisk was a member of numerous scientific, professional and social-economic organizations. He began his life's work after graduation as an honor student from the University of New York in 1888, and after a few years in private practice went with the Equitable Life Assurance Society. He was appointed Medical Director of the Provident Savings Life Assurance Society in 1898. Here he organized the first periodic health examinations and education services established by any life insurance company. His publications show, likewise, that he took a keen and intensive scientific interest in the data secured from nearly a million phys-

ical examinations conducted by the Life Extension Institute. He developed the sinister significance of "silent sickness" in marring life and its span, and hence the stress on periodical physical examinations, especially for those in mid-life and beyond.

He is survived by two daughters and three grandchildren. Brief funeral services held in Dresden were attended by the American Consul General and many officials and physicians, while burial services were completed in Brooklyn, July 30. Among the honorary pall bearers were a considerable number of members of the American Public Health Association.

It seems hardly fit to close without emphasizing Dr. Fisk's point of view on industrial fatigue, namely, continuous research along physiological and psychophysiological lines, with far more stress on intrinsic or bodily causes than extrinsic or environmental causes, and the reader will be well repaid in reviewing the last report of his committee in the Association's *Yearbook, 1930-1931*. The August issue of *How To Live* is devoted to press comments on Dr. Fisk's life and achievements.

Report of the Division of Occupational Diseases, Connecticut State Department of Health, 1930—With an appropriation of \$27,002.25 for the 1929-1931 biennium, the Division of Occupational Diseases, composed of a director, an industrial hygienist, and a secretary, made 81 surveys and 25 studies of industrial conditions during the year 1930, and compiled data on 485 cases of occupational diseases reported. The state has an estimated population for July 1, 1929, of 1,641,313, and is divided into 8 counties, some of which are busy industrial centers.

It was also found that about 200 cases of occupational diseases which were reported for compensation, according to the files in the Superior Courts,

had not been reported to the division. Each of these had lost at least a week's time, from which it can be judged that there were many more cases than those reported. A slight modification of the so-called "standard report form" for occupational diseases is required to be filled out by physicians having knowledge of such cases.

The technical part of the work was organized as follows: (1) Survey of industries where potential occupational disease exposures exist and studies in plants presenting actual hazards; (2) making surveys requested by industry and studies where necessary; and (3) working out, in laboratory, technical details for particular studies.

To facilitate this program, a classification or codification of Connecticut's industries was effected, dividing them into about 100 groups. Likewise, potential hazards have been codified, there being about 70 of these (copies of forms, and tables are presented).

The division made 278 field trips and 145 visits to industries in addition to surveys and studies above enumerated, and during the year 33 towns in the state were visited.

The surveys included such matters as general hygienic conditions, spray coating, sandblasting, chromium plating, buffing and polishing, benzol poisoning, carbon disulphide, occupational dermatitis, radium, sulphur dioxide, vitreous enamel spray and hydrogen sulphide. Certain educational activities were likewise carried on and a number of prominent persons visited the division during the course of the year.

It is felt that the work of the division has now grown to such an extent that more assistance is necessary even to meet the request for studies and surveys coming from industrial sources.—Albert S. Gray, Chief, Division of Occupational Diseases. *Report of the Connecticut State Department of Health*, 1930, pp. 249–277. E. R. H.

Benzene (Benzol) Poisoning—

This is an attempt to summarize what was published to December, 1930, regarding the action of coal tar benzene, C_6H_6 , on animals and on human beings. The effect of large doses resulting in acute poisoning can be considered fairly briefly; the more important action of small doses administered over long periods of time has been far more extensively studied, and here there are many records of experiments on animals and also of the experimental use of benzene in the treatment for leukemia. There are also a fair number of careful clinical histories of chronic benzene poisoning, always in industrial workers, and a small number of detailed reports of autopsies.

Under chronic benzene poisoning the discussion pertains especially to experimental poisoning in animals, a short review of experimental poisoning in man, and a considerable discussion of clinical observations and case reports, including recovery, and the influence on infections.

The pathologic anatomy with differentiations from other diseases of the blood and the findings of most recent investigators are all included. (The bibliography fills 5 complete pages.)—Alice Hamilton, *Arch. Path. & Lab. Med.*, 11: 434–454; 601–637 (Mar. and Apr.), 1931. E. R. H.

Board for Silicosis and Asbestosis

—A general medical scheme has been arranged by the British Government for coördinating the regulations for examination and certification under the different workmen's compensation schemes for silicosis and asbestosis. A medical board will act for the whole country and will be responsible for all the examinations and certificates required. Four local panels have been set up in the industrial areas concerned—at Newcastle-on-Tyne, Bristol, and Stoke-on-Trent.

A scheme has been arranged for the

asbestos industry and extended to the various industries in which silicosis occurs by which workmen who, though not totally disabled, are certified to be suffering from silicosis, to make it dangerous for them to continue in the processes; they shall be compensated.—London Letter, *J. A. M. A.*, 27, 2: 113 (July 11), 1931. E. R. H.

Colliers and Silicosis—Prof. S. Lyle Cummins (Cardiff), speaking on coal miners and tuberculosis, said that coal miners, although so constantly exposed to the inhalation of both coal dust and stone dust, are notoriously less liable to pulmonary tuberculosis than the rest of the adult male population in Great Britain. There is, however, a high death rate of colliers from bronchitis.

A large proportion of elderly coal miners are affected with a degree of silicosis which though not sufficient to prevent them from working is sufficiently advanced to give rise to the radiological appearances characteristic of lung fibrosis; such men tend to be short of breath on exertion and are liable to have a cough and bring up rather copious sputum, often black in color; they are also subject to fairly frequent attacks of catarrh.—Annual Congress at Frankfort-on-Main, Royal Institute of Public Health, *Lancet*, 5625: 1367 (June 20), 1931.

E. R. H.

Silicosis in Ohio Industries—Sixty cases of silicosis from 26 localities were presented in this study, half of them with photographs of X-ray films, presented or loaned to the author by hospitals, radiologists, and physicians in certain centers. Thus, in all cases the victims were seeking medical aid, usually for shortness of breath, general fatigue, etc. Many of the cases were first diagnosed as to tuberculosis, chronic bronchitis, asthma, etc., but the history of the occupation coupled with radio-

graphic findings rendered diagnoses of silicosis possible in all cases included in the study.

These cases represent 15 industries. Twenty-four of the 60 cases were sand-blasters, 22 of which averaged 45 years of age and 7.7 years of occupational exposure (in 2 cases these data were not supplied). This was the shortest occupational life period in the group. Seven were granite and marble cutters averaging 53 years of age and 26 years of occupational exposure. Six were metal grinders and polishers averaging 55 years of age and 20 years of occupational exposure. Six were pottery and porcelain workers averaging 51 years of age and 28 years of exposure—the longest occupational life period. Autopsy findings substantiated the diagnosis in 4 cases. Tuberculosis was found to be a common complicating disease in these cases of silicosis, being present in 23 out of the 60 cases.

Full-page, half-tone photographs of X-ray chest films are presented with the thesis, the first one of which is that of a normal chest in a blacksmith in a stone quarry, 53 years of age, used for contrasting the other photographs shown.—B. E. Neiswander, Thesis for the M.Sc. degree, Ohio State Univ., 94 pp., 31 plates; also tables (June), 1931.

E. R. H.

Comparative Cost of Maintaining Health Departments in Michigan Industrial, Public Utility and Mercantile Establishments—

Number of Employees	Cost per Employee
20,000 to 25,000	\$7.28 per year
10,000 to 19,000	6.87 " "
5,000 to 9,000	5.78 " "
2,500 to 4,500	5.20 " "
1,000 to 2,400	7.37 " "
500 to 900	6.29 " "
200 to 485	8.93 " "
Average cost for each employee	6.95 " "

Less than one-third of the establishments surveyed could give reliable fig-

ures on the cost of maintaining the health departments in their plants. Many did not keep accurate account of certain items, but all declared: "The well organized health department is worth while at any cost."

The cost of the health service through the plant first aid or health departments, as reported by individual firms, ranged from \$2.47 to \$22.00 per employee per year. The plant in which the cost was \$22.00 per employee averages 1,900 employees; has full-time medical service by employing 2 physicians, each serving $\frac{1}{2}$ day in the plant; has 3 nurses in the plant and 1 full-time visiting nurse; a fully equipped industrial hospital—eye room, dental room, X-ray and physical therapy rooms; requires careful physical examinations of all new employees and periodic health examinations. This plant has discovered a number of active cases of tuberculosis and taken steps to have all of them hospitalized. It reports also that in 2 years' time the average lost time by illness has been reduced from 8 to 3.4 days per employee, and no days lost from infections.

Another firm with 3,500 employees, 1 part-time physician and 4 nurses in the plant, stated that absences from illness have been reduced 49 per cent during the last 2 years, since establishing their visiting nurse service, to which they credit much of this improvement.

Ten per cent of the plants included in this report have 1 or more physicians engaged for full-time; 40 per cent have 1 or more physicians on the part-time plan—1 to 4 hours in the plants; while 50 per cent have physicians engaged "on call" only, most of them on the "service fee" basis.

Of the plants with 10,000 to 25,000 employees, 100 per cent have full-time physicians and 2 to 6 nurses in the

plants; 50 per cent have visiting nurses.

Of those with 1,000 to 9,000 employees, 36 per cent have certain physicians on call; $30\frac{2}{3}$ per cent have part-time physicians and $33\frac{1}{3}$ per cent have full-time physicians. These plants have from 1 to 5 nurses in the plants and 26 per cent have visiting nurses.

Of the plants with 200 to 900 employees, 80 per cent have physicians on call, and 20 per cent have part-time physicians, no full-time physicians; 60 per cent have 1 nurse each in plant and 40 per cent depend on first aid workers.

In the plants having from 200 to 485 employees wherein there are the least adequate provisions for health service, the cost is highest.—Frank A. Poole, Director, Bureau of Industrial Hygiene, Michigan Department of Health, 1 page mimeographed (July), 1931.

E. R. H.

The Measurement of Physiological Values in Industry—A standard for nomenclature for classifying industrial employees physically and the technic of charting functional capacity are principal features of the paper. The psychological technic involves the interviewer, precautionary "don'ts," the conduct and scope of the medical examination, and standardization.

The physical technic concerns the type of instruments needed and a classification of the defects found—five classes being recommended.

A physician's key for correct technic in measuring and classifying functional capacity constitutes the major portion of the paper, which is accompanied by an infolded sample chart arranged for 16 physical examinations on the same individual. The chart is suggested as a standard form for adoption in industrial medical services.—M. E. Fulk, *J. Aviation Med.*, 1, 4; 237–294 (Dec.), 1930.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Studies on the Effects of Overdosage of Vitamin D. II.—Experiments have been conducted showing that extreme overdosages of vitamin D had a peculiar action on the mineral metabolism of white rats and that increasing the dosages beyond a certain minimum caused a decrease in the ash of the long bones of the rat (*J. Biol. Chem.*, 84: 487, 1929; 86: 245, 1930).

The animals used in the experiment reported here were classed in 4 groups: Group I consisted of 9 third and fourth generations of young rats whose progenitors had received 40 units of vitamin D daily. These animals were placed on the same basal ration with the addition of 6,000 units of vitamin D in the form of dry irradiated ergosterol crystals. At the end of 3 weeks the animals were killed and autopsied and the specific organs and bones analyzed for ash content. Group II consisted of 6 adult second and third generation animals from the lot receiving 40 units of vitamin D daily. Group III consisted of third and fourth generation young animals whose progenitors had received 2,500 units of vitamin D daily. Most of the animals in this group died from the toxic effects of overdosage. Group IV consisted of 8 normal young animals to each of which were administered 10,000 units of vitamin D daily for 2 weeks. A table is given showing the analyses of bones and organs from all groups.

Dosages of 40 units of vitamin D daily were found to have no effect on the mineral metabolism of white rats when continued through the third and the fourth generations. No pathological calcification occurred and the ash of

the bones was normal. The animals which received a moderate overdosage of vitamin D for a long period of time were more susceptible to a massive overdosage than normal animals.

A large overdosage (2,500 units) of vitamin D just insufficient to produce toxic symptoms in the first and second generations, given for a long period of time, produces the following changes in the third and fourth generations: (1) decalcification of the bones, (2) severe calcification of the bones, (3) severe calcification of the kidneys, and (4) certain pellagra-like symptoms, namely scabby conditions of the feet, nose, and forequarters.—Robert F. Light, Glenard E. Miller and Charles N. Frey, *J. Biol. Chem.*, 92: 47 (June), 1931.

Fat Soluble Vitamins. XXXII. The Distribution of Vitamin A in Tomato and the Stability of Added Vitamin D—In this paper the literature on the vitamin content of tomato has been reviewed. The object of this experiment was to determine how small an amount of tomato would be required to furnish the rat with sufficient vitamin A. Seventy-five white and piebald rats, 3 weeks old and weighing 50 gm., were used. They were fed a vitamin A free basal ration consisting of alcohol-extracted and heated casein 18; salt No. 40, 4; agar 2; yeast 8; dextrin 68. The ration was supplied with vitamin D by treating with ultra-violet light from a Cooper Hewitt quartz mercury vapor lamp.

The animals were fed as much of the ration as they cared to consume. Symptoms of ophthalmia appeared at the 4th or 5th week, but occasionally at the 3d

or 4th week, after which decline in weight followed.

When the ophthalmia gave indication of being permanent the rats were taken for test. They were given small amounts of tomato preparation in addition to the basal ration. Charts are given showing the rate of cure of ophthalmia on whole tomato and on tomato serum.

Recovery from ophthalmia was very slow, when the whole tomato preparation was $\frac{1}{8}$ c.c. daily. On $\frac{1}{4}$ c.c. of tomato daily, ophthalmia was completely cured in 10 weeks and on $\frac{1}{2}$ c.c. by the 8th week. On 1 c.c. of the tomato serum the animals all died by the 5th week. On 2 c.c. one animal died during the 6th week. On 4 c.c. one animal died during the 4th week and the others improved very slowly but died in the 11th week. It will be observed that the whole tomato contained about 32 times as much vitamin as the serum.

Experiments were also made to determine vitamin D, and tables are given showing the calcifying action of tomato alone and of tomato and ergosterol. Vitamin D added in the form of irradiated ergosterol was found to maintain its activity after sterilization followed by 13 months' storage at 37° C.—H. Steenbock and Inez M. Schrader, in coöperation with Blanche M. Riising and Alice M. Wirick, *J. Nutrition*, 4: 267 (July), 1931.

The Effect of Desiccation upon the Nutritive Properties of Egg-White—In a paper by Boas (*Biochem. J.*, 21: 712, 1927), it was shown that dried egg-white, when used as the sole protein in a diet for young rats, produces symptoms such as dermatitis, baldness and spastic gait which terminated in death in from 4 to 6 weeks. It was further shown that these symptoms could be prevented if substances such as yeast, potato, arrow-root, and fresh egg-white are added to the diet. Two

hypotheses were advanced as possible causes: (a) that dried egg-white is lacking in some essential dietary factor, which is supplied by protective factor X; and (b) that a toxic substance is formed in dried egg-white as a result of desiccation, and that this is neutralized in some way by protective factor X.

This paper is concerned chiefly with a series of tests, some of a curative and some of a preventive nature, in which the effects of using some of the different constituents of egg-white, fresh or dried, as the source of protein were investigated. A table gives details as to the different diets used. All egg-white diets were dissolved in water and coagulated by heat before incorporation in the diet.

Each rat received with the diet 3 to 5 drops of cod liver oil daily. Crystalline ovalbumin was used as the sole source of protein in the diets of 2 rats which developed the usual symptoms after receiving dried egg-white diet for 8 weeks. Their condition improved and rapid growth followed. From the results here obtained it appears that when egg-white is dried some toxic substance is formed.

According to Hektoen and Cole (*J. Infect. Dis.*, 42: 1, 1928), there are five different proteins in egg-white—ovoglobulin, conalbumin, ovalbumin, ovomucin, and ovomucoid. Each of these was examined separately in an effort to determine from which protein the toxic substance is derived. The results obtained indicated that neither of these products contains toxic substances. It is concluded, therefore, that during desiccation of egg-white a toxic substance is formed from some non-protein constituent and that this substance remains present in the mother-liquor after removal of the proteins by precipitation with ammonium sulphate. However, the experiment has not yet been carried out to establish this belief.

It was found that rats suffering from the effects of the dried egg-white can

become spontaneously refected and that this condition can be transmitted from one rat to another by ingestion of the feces. Refection can be induced in rats, receiving the dried egg-white diet, by feeding the bulky white feces of refected rats on diets deprived of B vitamins. This suggests that the agency is the same in both cases.—Margaret Averil Boas Fixsen, *Biochem. J.*, 25: 596, 1931.

The Effect of Pasteurization upon the Vitamin C Content of Milk in the Presence of Certain Metals—This paper reports the results of studies as to the effect on the vitamin C content in pasteurized fresh milk aerobically in aluminum, in tinned copper, and in copper tubular pasteurizers. Six groups of animals were used, as follows: (a) a negative control group received no supplementary milk, (b) an autopsy control group was fed spinach as a source of vitamin C, (c) a standard comparison group received graded doses of raw milk, (d), (e), (f) three groups received graded doses of milk pasteurized respectively in aluminum, tinned copper, and copper.

Young male guinea pigs, weighing 200 to 240 gm., were placed on a basal ration with 35 gm. of fresh spinach and 10 to 30 c.c. of fresh, whole milk daily. The tables showing results of the experiments with the different dosages of raw milk indicate that 35 c.c. of the raw milk were not sufficient to protect the animals from scurvy and that there was about a 20 per cent deterioration in the

quality of the milk as the season advanced.

The effect of pasteurizing milk in tinned copper was slightly greater than that found with the aluminum, the effect being noticeable both during the progress of the experiment and upon post-mortem examination of the animals.

The pasteurization of milk in naked copper resulted in a destruction of at least 80 to 90 per cent of the anti-scorbutic vitamin, but all of this percentage cannot be charged to copper since the exposure to copper and the aerobic pasteurizing process both tend to destroy the vitamin.

The practical importance of these experiments is that copper is again shown to be unsuited for construction of dairy equipment so far as conservation of vitamin C is concerned. Tinned copper is unsatisfactory because of the impracticability of replacing worn inaccessible parts of equipment. As regards the destruction of vitamin C, aluminum is as satisfactory a material as there is for dairy equipment. These experiments are not inconsistent with the theory that anaerobic pasteurization would reduce the vitamin destruction even in the case of copper.

The authors point out that even though the vitamin destruction were reduced, from a public health standpoint great care should be taken in securing construction material with the greatest negative potentialities.—E. W. Schwartz, F. J. Murphy, and Gerald J. Cox, *J. Nutrition*, 4: 211 (July), 1931.

CHILD HYGIENE

RICHARD A. BOLT, M. D., DR. P. H.

HEART DISEASE IN CHILDHOOD

THE prevention of heart disease in childhood continues to challenge our best efforts. Since the epoch-making work of Sir James MacKenzie we have gained a clearer conception of heart disease, especially as it shows itself in the early stages. Great improvement has taken place in the classification and diagnosis of heart disease due largely to the painstaking studies of the American Heart Association and the Heart Committee of the New York Tuberculosis and Health Association.¹ While our methods of diagnosis have become more refined and exact, our knowledge of the underlying causes of heart disease and its prevention has lagged.

It is true that now we possess a better view of the heart as a functioning organ and of its ability to adjust itself to varying loads. The recognition of the protean character of heart disease was a decided step forward in view of its changing character at different age levels. It is generally accepted that rheumatic fever with its accompanying conditions is the main etiological factor in heart disease of childhood. While there is still some question as to the relation between focal infection and rheumatic fever, Coombs² considers rheumatic fever as an infection by "microorganisms that do not seem to be radically different from the streptococci that inhabit the normal mouth . . . the soil is as important as the seed. The healthy child does not become rheumatic because of bacterial visitation but because of defects of inheritance and environment."³

There is a tendency to accentuate the darker side of heart disease as seen in adults and to overlook the possibilities of prevention in childhood. The usual somber picture of heart disease presented in current literature is that of a disease with rapidly increasing death rate about which we apparently can do very little if anything. This viewpoint arises largely because we have set before us the crude death rates from heart disease with little or no analysis as to age distribution.

It is certainly true that the crude mortality rate for heart disease has been increasing, but when this is carefully studied it is seen that the increase has taken place mainly after 40 years of age. Analysis of the death rates under this age reveals that there has been a decided decline at all age levels, especially under 10 years of age. In view of the fact that our methods of diagnosis have become more refined and that parents generally are having their children examined periodically by competent physicians one must consider the decline in heart death rates at the lower ages as quite significant. It simply means that we are saving more and more children to live up to the period when heart disease takes its largest toll.

It is not the death rates alone which should concern us. There is evidence to show that the diseases leading to heart disease are slowly coming under the control of preventive medicine. The prevalence of those diseases associated with heart disease in childhood has diminished during recent years. Rheumatic fever, long looked upon as

the greatest cause of heart disease in children, is apparently on the decline in many parts of this country. While there is still some debate as to the etiology of rheumatic fever itself, there is practically unanimity that it is a general infection attacking those with a "rheumatic constitution." At any rate it manifests itself in various ways depending upon the tissues attacked.

We have long regarded chorea, "growing pains," polyarthritis, tonsillitis, and pharyngitis as rheumatic manifestations which may be precursors of organic heart disease. These conditions in children are undoubtedly becoming less prevalent in many localities. We should also remember that other acute infections such as diphtheria and scarlet fever are either being reduced considerably or now appear in milder types. If focal infections in teeth, tonsils, sinuses, etc., have any bearing upon heart disease, as many believe, it must be recognized that these conditions in children are receiving more rational and thorough treatment than ever before.

Another fact which stands out prominently is that with increasing care in the examination of larger and larger numbers of infants, preschool and school children, there appears to be no increase in the percentage exhibiting organic heart disease. It is true, of course, that congenital anomalies of the heart continue to occur in about the same proportion as formerly, but these form such a small percentage of the total that we can practically leave them out of consideration.

When we come to consider children under 2 years of age who have not been hampered with congenital heart disease, we find that very few of them present any serious heart trouble. Careful examination of a large number of young children in our infant welfare centers reveals comparatively few with organic heart disease. Aside from those with

congenital deformities of the heart the death rate from heart disease under 5 years of age is relatively low.

When we consider the children of school age we find quite a diversity of figures presented. It is extremely difficult, if not impossible, to obtain comparable figures from different school reports. This is easily understood when we take into consideration the marked differences in methods of examination and reporting of heart disease. The figures range from 0.5 per cent to 1.5 per cent of the school children examined as having some form of heart disorder. The organic forms of the disease are not clearly differentiated from the functional in many of the statistics. Where painstaking examinations are made the percentage of organic lesions range from 0.3 per cent to 0.5 per cent in the elementary schools. There apparently is a very slight increase in the secondary schools. In children applying for work permits from 1 to 2 per cent show some heart defect, with about one-half of an organic nature.

From the data available one must draw the conclusion that while heart disease is a potential danger during the school age, it is by no means as serious as we have formerly been led to believe. We should especially be concerned, however, during the adolescent period as this is the time the heart is often put to considerable strain. Children returning to school after one of the infectious diseases should be carefully watched before being allowed to go into strenuous exercise.

Some very interesting data as to heart disease as a cause of death in children under 14 years of age appear in a recent contribution by Epstein.³ He reviews the results of 1,000 consecutive autopsies upon children. Of this number there were 68 cases of acquired heart disease of which 36 were in children with a definite history of rheumatism. The distribution of the lesions

found were as listed below:

Mitral valve alone	19
Mitral and aortic	12
Mitral and tricuspid	7
Mitral, tricuspid & aortic	5
Mitral, aortic & pulmonary	4
Mitral, pulmonary & tricuspid	2
All four valves	2
Tricuspid alone	2
Aortic alone	1
Pulmonary alone	1
Fibrous Adhesive Pericarditis	35
Purulent Adhesive Pericarditis	15
Serous Pericarditis	7
Fibrous Pericarditis without endocarditis	9

The question of the relation of tonsils and adenoids to the health of children has often been raised and discussed. Some years ago Kaiser published the results of the removal of tonsils and adenoids of children going to the Rochester Dental Infirmary. In certain respects his figures at that time were inclusive. He has recently published another paper of much wider scope based upon a control study of 4,400 children over a 10-year period.

This study suggests that certain infections have a close relationship to the presence or absence of tonsils and adenoids. Other infections are not influenced favorably or unfavorably by the presence or absence of lymphoid tissue. A few infections seem definitely more common in the absence of tonsils.

The removal of tonsils and adenoids influences favorably the incidence of the following infections: (1) colds in the head, (2) sore throats, (3) cervical adenitis, (4) otitis media, (5) rheumatic disease: The first attack of rheumatic fever and rheumatic heart disease occurred 33 per cent less commonly in tonsillectomized children. Chorea and recurrent attacks of rheumatic fever were not influenced by removal of the tonsils. (6) Diphtheria, (7) scarlet fever, (8) nephritis, (9) dental infections: such infections occurred only half as often in the children whose tonsils and adenoids had been removed.

The following infections were influenced favorably to a slight extent: (1) chorea, (2) measles, (3) laryngitis, (4) tuberculosis, (5) malnutrition.

The removal of the tonsils and adenoids influenced unfavorably the incidence of the following infections: (1) bronchitis, (2) pneumonia, and (3) sinusitis.⁴

Other studies are to be desired along this same line, especially as to the relation of removal of tonsils to rheumatic fever.

LESSONS FOR THE EXPECTANT MOTHER

IN 1922 Ellen D. Nicely, R.N., initiated an important piece of prenatal work in the University Public Health Nursing District of Cleveland, O. A course of plain talks and simple demonstrations was organized for mothers attending the newly established prenatal clinic of the Maternity Hospital of Western Reserve University. This proved of so much service to the expectant mothers and held out so much promise that Virginia Wing, secretary of the Health Education Committee of the Cleveland Health Council,

assisted Mrs. Nicely in setting up a number of prenatal institutes throughout the city where she could extend her instruction.

In 1926 a Prenatal Committee of the Cleveland Health Council sponsored this work and made possible a number of prenatal classes in different districts of Cleveland where expectant mothers could receive instructions with practical demonstrations. These classes were approved by the Academy of Medicine of Cleveland as they were acceptable to the foremost obstetricians in the city.

Mrs. Nicely then drew up a series of simple lesson outlines for use in her prenatal classes. To these she added further lessons in habit formation and mental hygiene prepared by Mrs. Gary Myers. These were reviewed and approved by a group of the leading obstetricians in Cleveland connected with obstetric services of hospitals of Cleveland. The lessons were printed in mimeograph form and were widely used throughout the city.

Three years ago the Cleveland Health Council recognizing the great value of this project and considering it important enough to be integrated with the maternity services carried on in the community, turned it over to the Maternity Hospital with its 8 prenatal centers, and at the same time made the service available to St. Luke's, Mt. Sinai, and Huron Road Hospitals. Since then

Mrs. Nicely has extended her group teaching, including in it lessons in mothercraft. Last year over 3,000 prospective mothers were reached. Of these mothers coming to confinement only one maternal death occurred. This certainly speaks eloquently for the value of such group instruction.

The lesson outlines have proved so helpful that it was decided to make them available in more permanent form to every organization in the community and to physicians and nurses who may care to use them. The Cleveland Child Health Association has had these outlines reprinted with attractive illustrations and is offering them for wider distribution. A copy of the *Lessons for the Expectant Mother* may be obtained upon request from the Cleveland Child Health Association, 621 Federal Reserve Bank Building, Cleveland, O.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

The Public Health Nurse and Cancer—Because the public health nurse comes in closer contact with more members of the family than perhaps any other individual she ranks high as an agent in cancer control. If she is "cancer conscious" she is able to uncover many early cases of this disease through her close contact with and observation of apparently trivial symptoms in her patients.

The public health nurse should have a considerable knowledge about cancer and how it should be handled, because cancer ranks second as the cause of death in the United States and she is

interested in health, also because most of the lay public have a particular dread of this disease.

The public health nurse is a trained observer. She can note the warty growth, the open sore or small ulcer, the scaly patch, the lump on the neck, the black or brown mole, all danger signals which need to be investigated and at least proved that they are not malignant.

As confidant of family abnormalities she also hears of symptoms which mean an early sign of cancer, like irregular uterine bleeding, blood in the urine, a lump on the breast, etc. Usually it is doubly hard to get patients with these symptoms to seek medical consultation because no pain is present. These symptoms may not mean cancer, but it

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

is the duty of the public health nurse to see that the patient receives an examination by a competent physician, to eliminate the possibility of cancer.

Many physicians are not qualified to determine whether or not a patient has cancer in its early stages, but by inquiring into the manner in which the examination was made (sometimes medicine is given without an examination) the nurse can get a pretty good idea of the reliability of the opinion given by the medical man. She knows something about the value of the cystoscope, the proctoscope, the laryngoscope, the speculum and digital examination. Sometimes if she feels that the opinion of one medical man has given the patient a false sense of security she should advise him not to be satisfied with one opinion in so important a matter.

Even after the patient has consulted a physician about some suspicious lesion, she must follow him up, see what the physician has advised and see that the patient follows this advice. She can explain why the physician wishes to take a section of the tumor or ulcer for examination, why the physician is the best judge of whether surgical methods should be used or not, and why the quack doctor can do untold harm in treating cancer. She can enlighten the patient somewhat on the use of electrical treatment and radium.

The nurse cannot recommend a physician even though she knows the patient cannot very well judge what physician is or is not qualified to give radium treatment; but she can "be prepared to offer a list of specialists competent to treat cancer, and inform herself on the clinic facilities available for those unable to go to private physicians."

The hope of curing cancer lies in early discovery, so the public health nurse is justified in taking special care to see that the cancer sufferer obtains correct treatment at the start of the disease. On her rests a grave responsi-

bility to increase her value through her knowledge of cancer, since she will often be the "first contact between the early cancer case and the path which leads to proper treatment."—Ellis Fischel, *The Public Health Nurse's Responsibility in Relation to Cancer*, *Pub. Health Nurs.*, XXIII, 7: 334-337 (July), 1931.

The Vassar Training Camp for Nurses Has a Lasting Memorial—On June 24, 1918, 435 young women, graduates of 115 colleges and universities from all over the United States, with a few from Canada, gathered on the campus at Vassar College. At the same time came a faculty of fifty or sixty which included such scientists as Florence R. Sabin, M.D., of Johns Hopkins, C.-E. A. Winslow of Yale, Otto K. O. Folin of Harvard, William H. Park, M.D., of the New York City Laboratories, Margaret E. Washburn of Vassar, and other teachers of science from various colleges and medical schools. There were also instructors from the nursing schools of Bellevue, Johns Hopkins, New York, Presbyterian, St. Luke's, Hunan-Yale, and other great hospitals. These constituted the "Training School for Nurses at Vassar College" suggested by an alumna and trustee of Vassar College, Mrs. John W. Blodgett, endorsed and recruited by the alumnae of Vassar as their most important war work, accepted by the college trustees, and backed financially by the American Red Cross.

The curriculum of the course was devised by such prominent members of the nursing profession as M. Adelaide Nutting and Isabel M. Stewart of Columbia University and representing Natl. League of Nursing Education; Dean Annie W. Goodrich of the Army School of Nursing; Jane E. Delano of the American Red Cross; superintendents of hospital nursing schools like Miss Maxwell of Presbyterian, Miss Hilliard

of Bellevue, Miss Clayton of Philadelphia General, Miss Gray of City of New York, Miss Wood of Massachusetts General at that time, Miss Johnson, then at Albany, later of Massachusetts General, and Miss Logan of Cincinnati General. These women all assisted in the organization of the Camp. Herbert E. Mills, professor of Economics in Vassar, was entrusted with the organization and administration of the Camp with the title of Dean.

The plan in brief was a 3-months intensive training in fundamental sciences—anatomy and physiology, bacteriology, chemistry, elementary materia medica, nutrition and cooking, history of nursing, elementary nursing procedures, psychology, social economics—on the Vassar campus.

At the end of this period training was to be completed in leading hospitals over the country of which over 40 had agreed to coöperate. Students took an average of over 30 hours a week in lecture, laboratory and hospital practice ward. Their ability, enthusiasm and fine spirit made this a wonderful group.

Of the 435 all but 17 finished the hard summer's work; and for most of the 17 who withdrew there were good excuses such as illness or family deaths. About 400 entered their hospitals as probationers in September. Almost at once they were plunged into the horrors of the influenza epidemic, rendering invaluable service in that calamity. Five died during it and 2 later because of its results. Right after the epidemic came the armistice, and as patriotic service in time of war was uppermost in the minds of these nurses a number withdrew shortly after peace was declared. But despite influenza and peace, nearly half of those who entered hospitals finished their training and became registered nurses.

At a reunion held at Vassar at Thanksgiving time, 1920, attended by many of the nurses and a good number

of superintendents of nurses from various hospitals, a very frank but good natured discussion of nursing education and hospital conditions took place, illuminating to officials as to the reaction of intelligent young women to the existing situation, but equally so to these young women as to the difficulties under which superintendents labored.

What has become of this group? Among them are superintendents and instructors in nursing schools, directors of university public health nursing courses, directors of public health nursing associations; teachers of hygiene in normal and other schools. With few exceptions they are all holding executive positions in nursing. They have been called to China, to South America, to Europe. Many have married and assert that what they learned at the Camp was the best possible preparation for home keeping and motherhood. Over and over they declare that that summer was the greatest experience in their lives.

To commemorate the Training Camp for Nurses a beautiful gateway to the college campus has been constructed, and it was dedicated June 8, Vassar's Class Day. Escorted by the senior class in their Class Day attire, singing marching songs, officers and students of the Camp marched to the gate where brief speeches were made by Mrs. Blodgett, President MacCracken, Mrs. Priscellia Barrows Sheldon, a student in the Camp, and Dean Mills. Part of the cost of the gate was met by students who had been connected with the Camp. By vote of the Vassar trustees the gate is to be called "Mills Gate" in honor of him who administered the undertaking and who has just retired from the college faculty after 41 years of service.

Public Health Nursing Records—
The never ending bugbear of most public health nurses is the record they are asked to make of their work. Often in

the press of duties they forget how vital records can be made, that they are not an end in themselves, but a means to an end.

In his recent book *Health on the Farm and in the Village*, Dr. Winslow cites an analysis of the use of records from the Manual of the Visiting Nurse Society of Philadelphia.

Nursing records are of value:

- A. To the Nurse, making her services to the family more complete—
 1. By helping her to be observant of all the factors that might affect the health of the family.
 2. By revealing the need of health work in each family and giving evidence of what is being accomplished.
 3. By constituting a summary of conditions found and of action taken.
 4. By improving the quality of the nurse's work, since the records also show what is being left undone.

5. By saving duplication and waste of effort, since they enable one nurse to begin where another has left off in work with any family.

B. To the Organization—

1. By helping in the supervision of work, thus making it doubly possible to do thorough and complete family health work.
2. By helping to show how far the organization is meeting the needs of the community and where further development is desirable.

C. To the Public—

1. By providing valuable material for morbidity and mortality statistics.
2. By showing what are the greatest health needs of the community.
3. By showing the social as well as the medical causes of sickness.
4. Through such statistical material it may be possible to get community or legislative action to remedy conditions.—

C.-E. A. Winslow, *Health on the Farm and in the Village*, 1931, pp. 175, 176.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Dr. Lee K. Frankel—It is but fitting that this department should add its modest mead of appreciation of Dr. Frankel, the first formally elected chairman of the Public Health Education Section of the A. P. H. A.

More than any other one person, Dr. Frankel has initiated or sponsored various forms of effort for large scale "mass education" in health—in variety, extent, and unusually high average of quality.

The continued development of the health education projects of the Metro-

politan Life Insurance Company even beyond its present wide usefulness and extent will be an appropriate memorial to Dr. Frankel.

Today—If Not Already Done—If you have any health education-publicity material which should be displayed at Montreal, now is the last chance to send it. Address: Montreal Display, Evart G. Routzahn, 130 E. 22d St., New York.

Facilities for Utilizing Health Advice—In a discussion of "the legitimate field of public health agencies," Dr. J. W. Mountin, U. S. Public Health Service, emphasized, possibly without

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

intention, the comparative futility of offering health advice which calls for facilities lacking in a given community.

The health of the individual depends on his own efforts in a suitable environment. It is not sufficient that he understand the rules governing health and be willing to observe them; certain facilities must be made available to him. While measures for the prevention of disease and promotion of health find application in almost every phase of human activity, yet their full development will not be realized in any given community until some organization accepts their promotion as a major responsibility.—

Changing Status of Health Officer.
Ill. Health Quarterly, State Dept. of Public Health, Jan.-Mar., 1931. See for facilities to be provided and relationships of health agencies and physicians.

Believe It—Or Not—Middletown, N. Y., in its *Health Bulletin* under the above title:

1. You can't get smallpox if successfully vaccinated within 7 years.
2. You can't get typhoid if you've had 3 doses of the vaccines.
3. You can't judge the safety of the cook by the neatness of her dress.
4. You can't have unreported and unquarantined cases of contagious disease in your home without endangering your neighbors and arousing their enmity.

Welfare and Relief Mobilization, 1931—1. In all probability in many parts of the country there will be increased efforts to cut down health and medical services along with all welfare activities except actual "relief." 2. More than ever before there will be increased need for these services during the financial emergency. 3. The Welfare and Relief Mobilization is a common effort, especially in cities of 25,000 and upwards, to strengthen the position of all existing services—public and private—and to expand them to

meet emergency demands. 4. Health education and publicity workers may help in this nation-wide crisis by unceasing care and skill in helping to explain all health and medical services in their states and cities. 5. Good ideas and material which might be used in other cities may be sent to your national association for this wider use.

However much conditions may change for the better this fall unforgettable experience in the past has shown that high tide in the need for relief will not come until months later.

The interpreters of public health need to be very much on the job—to protect all services now functioning, and to seek emergency extension of service where needed. Close coöperation between local health and social agencies, public and private, will increase effectiveness and lessen complications.

When Half a Million Were Taught in a Day—The official motion picture film of the Shanghai Cholera Prevention Parade, with coffins and man-size flies, and Chinese policemen carrying health and cleanliness banners, will be shown at the annual meeting of the A. P. H. A. in Montreal. W. W. Peter, M.D., Dr.P.H., technical adviser to the Chinese Ministry of Health, now on leave of absence from his post as director of Health Service of Cleanliness Institute and formerly, for 15 years, connected with the China Council on Health Education, will sail August 26 to bring the film to America and expects to be at Montreal to greet old friends and new. It is probable that Dr. J. Heng Liu, director of the Ministry of Health, will send one or more representatives of the Health Education Division along with Dr. Peter for further study in the United States.

Between half a million and a million people saw the parade in Shanghai on Saturday afternoon, June 6, and it proved so successful that plans are al-

ready under way to repeat it next year. Altogether fully 2,500 persons took part, including Boy Scouts and Girl Guides of many nationalities, medical students, and others. Dr. Peter writes:

The teaching principle followed was to show first the wrong way of living. Then came possible consequences carried on stretchers, and after several stretchers one or two coffins. Each unit was attended by megaphonists who explained the unit to which they were attached. Then followed a visualization of the same subject showing the right ways of living.

A few simple lessons, graphically and dramatically presented, were the center of this elaborate parade as they have been of the entire educational campaign of which it is only a part.

Cholera spreads from sick to well through water, food, fingers, flies. . . . Cleanliness prevents cholera. Keep your hands clean. Use only clean water. Eat only clean food. Keep your home clean.

Before the day of the parade 10,000 posters were put up, chiefly on municipal property where no other advertisements were allowed. These bore illustrations of sanitary conditions involving washing of hands before eating; control of flies, sputum, and garbage, etc. The text in Chinese, English, and French read: "It is easier to prevent than to cure! Fight against cholera." In addition 150,000 handbills were distributed along the line of march. Newspapers gave generous space to the whole project, especially the Chinese papers, of which a number in Shanghai attain national circulation. Now that the parade is past, the motion picture film is being distributed throughout China and is to be shown in India as well.—Florence M. Seder.

Telling the Other Fellow—Here is one kind of letter which helps get good radio hours for health talks:

Station XYZ:

That was a bully talk on diphtheria by Dr. John Smith Tuesday evening. I hope that you will give us more good speakers on health subjects.

James Brown

If you and I and other listeners will write letters now and then to broadcasting stations telling what health talks we like it will count in getting good time for more of them. If you don't like the talk, be very sure to tell the station what was wrong with it.

"Fan mail" has much to do with what broadcasting stations and newspapers offer their audiences. Should we leave the letter writing to the followers of comic strips and astrologers?

How Prominent People Help—As reported in *News Letter*, West Virginia State Dept. of Health (July 15, 1931):

During a recent campaign for smallpox prevention in Middletown, N. Y., the mayor, who heartily supported the movement, had himself and his entire family vaccinated. Pictures were taken of the local health officer and nurse administering the vaccine. These were published in the local papers, and later in New York State *Health Bulletin*.

This idea could be happily used in many West Virginia communities. When planning an immunization campaign not only secure the coöperation of the mayor but have him visit your office, bringing his family, if he has children or grandchildren, and get a picture of the vaccination in process. Do all this prior to the campaign. Then see if your local papers will carry this picture, together with the story of the campaign. If necessary pay to have the picture inserted.

Where you cannot get your papers to use it, have copies of the picture made (enlarged if necessary) and used on posters in a few prominent store windows. This will attract much attention and create favorable comment.

This same publicity stunt might be used in connection with other prominent people in the community, such as the superintendent of schools, the leading merchant, or wealthiest man in town. Another way is to have one class in the school or the whole school, with a per cent immunization against diphtheria, typhoid and smallpox or all three, photographed and the picture used in a prominent place with proper caption.

What Health Topics for Social Workers?—The National Conference of Social Workers has a Health Division, usually holding 5 sessions. What kind of public health material should be presented at a national gathering of social workers? What problems, possibilities and technics in the field of public health should be presented in meetings largely made up of non-public health workers? Send your suggestions to the chairman, Anna Drake, Public Health Federation, 312 W. 9th St., Cincinnati.

Nearly Every One a Quack Doctor?—In "Medical Amateurs," radio talk by Dr. H. W. Haggard, is a striking picture of the conscious and unconscious quack practice of medicine. Splendid material on which to base talks and copy, and a document for widespread distribution. The simplicity of the writing is almost a model for health educators. *Free* from Eastman Kodak Co., Rochester.

How to Get Copies—The names of periodicals referred to in this department usually appear in italics. When you wish to secure a copy containing an article mentioned in this department it is wise to *quote the reference in full*. Then you guard against omitting essential facts. Certainly mention the date when one is given. Usually a health agency will send free single copies of its own bulletin or house organ, and usually copies of a magazine of general circulation must be paid for. The editor will supply omitted addresses, and usually can loan a copy, but *address the periodical direct* if you wish a copy all your own.

ADVERTISING

"Health Claims in Advertising" (*Hygeia*, Aug., 1931) presents several points, good and bad.

The magazine advertisements of the Metropolitan Life Insurance Co. con-

tinue to be a major contribution to direct health education. And they should be illustrative of possibilities in the selection and arrangement of material for other forms of printed health education.

"Building the Fortresses of Health" is the general title of a portfolio reproducing a series of page advertisements issued by Parke, Davis & Co., Detroit.

To tell some of the fascinating stories connected with medicine—to give people a clearer understanding of what the recent advances in medical science mean to them and to their children—to portray the part played by physician, pharmacist, and maker of medicines in safeguarding the health and happiness of the nation and the world—to tell the public at large who we are and what we stand for:—

Presumably they are scientifically sound. Certainly they are admirable examples of what can be done with pictures and words to present health material in readable form. Address the Company for a free copy.

RADIO

"Some Diseases We Don't Talk About and Why Not" (venereal diseases), by Massachusetts Socy. for Social Hygiene, over WBZ and WBZA. Also 5-minute talk on syphilis over WNAC. Any comebacks, Mr. Kiernan?

Health broadcasting was reported by the U. S. Public Health Service at the World Association for Adult Education meeting in August in Vienna. We quote a few paragraphs from the manuscript prepared by Asst. Surg. Gen. R. C. Williams:

An inquiry sent to each of the 48 state health departments of the United States indicates that in 15 of these states the health department regularly issues broadcasts on public health subjects. Such broadcasts are usually issued weekly, twice a month, or monthly. Six state health departments issue broadcasts at irregular intervals. The earliest state broadcasting was begun in 1922. Several of the states have been engaged in this work for a number of years. The combined population of the states that issue broadcasts regularly is

approximately one-half of that of the United States.

An inquiry addressed to the city health department of the 200 largest cities of the United States indicates that 18 cities regularly issue public health broadcasts, which are usually issued weekly, twice a month, or monthly. Seventeen cities reported the use of the broadcasts at irregular intervals.

Forty-two county medical societies prepare and broadcast regularly programs dealing with public and personal health.

According to information obtained through the American Medical Association, there is 1 city in the United States that has a rather unique arrangement. The city medical society, in coöperation with the state medical association, conducts a weekly broadcast. This broadcast consists of questions and answers. This particular hour is called Doctor K-R-L-D. It is located at Dallas, Tex. Great numbers of letters have come to Doctor K-R-L-D for attention. They are an evidence of an interest of the public, not only of the State of Texas, but all over the United States. No one knows the identity of Doctor K-R-L-D, and no one is permitted to tell who does know.

Here is a first attempt to classify the forms possible in broadcasting. Additional items, or entire re-grouping of the forms will be welcome.

Talk or speech: alone, or with music, dramatics or other features.

Music: with credit for sponsorship by the agency, or with other features.

Dramatic: monologue, conversation or dialogue, or play.

Questions and answers: answers to questions from listeners; answers to a group of questions supposed to be of interest to the audience; test questions offered to the audience—to be answered next week; possibly with awards for answers from the audience; test questions put to a prominent person with his answers checked on the spot or checked by answers next week.

Please report on any of the above which you have already tested.

CONTESTS

The Massachusetts Society for Social Hygiene, 1150 Little Bldg., Boston, announces a competition to secure a suitable manuscript for publication on sex hygiene, designed for adolescent boys and girls. An award of \$500 is offered

to the author of the manuscript selected.

The society has in mind a pamphlet on the important subject of sex hygiene which will be useful in developing a rational attitude toward sex problems on the part of young men and young women between the approximate ages of 14 and 18 years.

Such a pamphlet should contain quite definite statements about the physiology and psychology of sex, including the various aspects of the sexual instinct, and should refer to the temptations and dangers of sex, to autoerotic activity, to the more common abnormalities, and to the venereal diseases.

Recognizing the fact that young men and young women of the present day are considerably advanced in their information about life and sex, and are subjected to many influences tending to undermine the wholesome and normal attitude so necessary to meet the problems growing out of sex in young adult life, this society believes that this subject should be handled in a straightforward manner which has not characterized the usual sex hygiene pamphlet of the past.

Five judges of outstanding reputation in the field of education and social hygiene will judge the manuscripts and make the award.

All manuscripts must be submitted not later than October 1, 1931, when the contest closes. The manuscript should contain from 5,000 to 6,000 words. The award of \$500 will be made January 1, 1932. Write for the conditions.

State and national winners have been announced in the third annual Gorgas Memorial Essay Contest. Address the Memorial at 1331-3 G St., N. W., Washington, for details. About 12,000 contestants in 43 states participated. This should mean that a significant amount of reading and study of health topics was done by high school students. We venture the suggestion that a much larger number will participate next year if the Memorial Institute can

see the way to offer simpler and more unified subject matter for the essays.

The Ohio Public Health Assn., Columbus, awarded a first prize of \$50 to D. L. Mansell, *Canton Repository*, for "the best Christmas seal editorial appearing in an Ohio daily." S. H. Green, *Putnam County Gazette*, did the best editorial in a weekly. Mr. Green is a farmer who writes for various country newspapers.

NEWSPAPERS

An important coöperating agency in health education is the Associated Press, which distributes to its member newspapers a 6-day a week health column. Known as "How's your Health?" the column is written by Dr. Iago Galdston, New York Academy of Medicine. It is distributed by the Associated Press Feature Service in sheet form, 14 days at a time, each column running about 8½ inches in length. Early August topics: Choosing a Sanatorium; Causes of Stuttering; Stutterers; Superstitions; Children's Sun Baths; Glaucoma; Blue Mondays; Light and Tuberculosis—I; Light and Tuberculosis—II; Soap and the Skin; Leaking Heart; Heart Disease; When They Won't Eat; Mother as a Nurse. The column is being used by about 300 newspapers in the United States.

Some health workers complain that some newspapers are unwilling to mention the venereal diseases, but in at least one city health department annual report we find the same inhibition. "Social diseases" is as far as that health officer will go!

WORDS

In a recent issue of *New York World-Telegram* says Heywood Broun:

An old pet theory of mine is being strengthened day by day. As a matter of fact, it has ceased to become a theory. By now it is a conviction. I refer to the almost universal tendency of writers—particularly young

writers—to say too much. . . . The true artist in any field gets the best results through an economy of words or motions.

A plea for short words—from *The Wedge*, issued by Batten, Barton, Durstine and Osborn:

The reason we use short words to talk with is that they mean exactly the same thing to talker and hearer. When we drag in a lot of jointed words, we forget before the sentence is finished just what it was we were trying to say; and the other fellow never does find out. For the same reason, we use short words to think with. . . . Short words are easy and pleasant to read. The eye picks up their meaning without conscious effort. But the average reader stumbles over pompous words and loses his mental balance. They annoy and bore him. After about two staggers, his interest wanders and he turns to the next page.

DIPHTHERIA

"The Milwaukee Health Department urges all parents to have their children protected against Diphtheria" on the back of the August quarterly bills from the municipal water department. Includes list of diphtheria prevention stations in the section to which the bills are addressed. *Sample, 2 cents.*

"Diphtheria Waning" is simply a large type table comparing cases and deaths for 1900, 1925 to 1930. Effective. On coverpage of *Monthly Bulletin*, Phila. Dept. of Health. June, 1931. *Free.*

"Interesting the Public in Diphtheria Immunization," by Dr. J. L. Rice. *Conn. Health Bulletin*, State Dept. May, 1931. *Free.* How it was done in New Haven.

EDUCATIONAL MATERIAL

"The Periodic Health Examination—The Keystone of Preventive Medicine," by Dr. D. B. Armstrong. Metropolitan Life Insurance Co., New York. *Free.* Reprint from *New York State Journal of Medicine.*

"Addressing Lay Organizations on the Health Examination," by C. Ward

Crampton, M.D., 515 Park Ave., New York. *Free*. Reprint from *New York State Journal of Medicine*. Addressed to county medical society members who may be invited to speak before lay audiences. Not too much material to overwhelm the busy practitioner.

From American Society for the Control of Cancer, 25 W. 43d St., New York:

Important Facts for Women about Tumors. 14 pages; dated.

What Everyone Should Know about Cancer. 24 pages; 4th edition; dated.

A reprint on the need of cancer services. Important; on glossy paper.

The Endowment of Cancer Control Activities. 14 pages; one of the unhappily few examples of dignified presentation of public health for appealing to large givers. *Copies of above free*.

REPORTING

Inspired, we believe, by the colorful graphic presentation of statistics by the group in Vienna, Dr. Lee K. Frankel, through his Welfare Division of the Metropolitan Life Insurance Company, set a new high for statistical presentation in this country. Seeing Is Believing (happy title!): A Campaign to Lengthen Life Told in Pictures is a 14-page pamphlet recording "a carefully planned, persistent campaign of health education and nursing care." Every reader will want a copy; *every reader may have a copy upon request*.

The 27th report of Visiting Nurse Assn. of Somerset Hills: "for purposes of economy this statement replaces the usual annual report." A 6-page folder; 3½" by 8½"; effective selection of essential information; some will argue that it is all that an annual report needs to be—if adequate month by month interpretation has preceded it. "15,445 miles were traveled by one nurse doing school nursing." No office address is given and N. J. is not mentioned. The Baldrige poster of the nurse (issued

by the N. O. P. H. N.) makes an attractive cover design.

Four pages of the 1930 report of Infant Welfare Society of Chicago contain a picture story of the services rendered. Two photographs (3 by 3½) on a page with descriptive caption in middle of the page do a good job of explaining. The text of the reports would attract more readers by the addition of subject headings. *2 cents*.

"Health history in the making"—white letters on red bands across the top and bottom of a 6-page folder, 4¼ by 9½, annual report of Queensboro Tuberculosis and Health Assn., 163-18 Jamaica Ave., Jamaica, N. Y. Several good inside features better seen than described. It is not dated. *Samples free*.

Reporting that "New Haven Wins First Place" in the Chamber of Commerce of U. S. A. contest, *Health*, New Haven Dept. of Health, devotes its May issue to a symposium of congratulation and interpretation by the city's leading citizens.

Births, Infant Mortality: Local Distribution in Bellevue-Yorkville Health Demonstration. B-Y Health Demonstration, 325 E. 38th St., New York. 9 pages of maps and statistical tables reproduced in a fairly inexpensive form for such detailed data. The Demonstration will supply information on request.

THEY BELIEVE IN EDUCATION

"Education the Need" is argued in "A Rational Dental Hygiene Program for Municipalities," by Dr. C. J. Hollister. *Pennsylvania's Health*, State Dept. of Health. May-June, 1931. *Free*.

HONORABLE MENTION

To Bombay Presidency Baby and Health Week Assn., Bombay, India: for annual report with a table of contents.

COÖPERATING GROUPS

The National Advisory Council on Radio in Education, 60 East 42d St., New York, is one of the newest coöperating agencies. Established to advance adult education via broadcasting the council will seek to further health and social welfare presentation by radio. Health and social workers may become associate members, subject to approval by the executive committee, without payment of a fee. Valuable publications have been issued and others are in course of preparation. Levering Tyson is the director and recently Curtis E. Lakeman has joined the staff. Mr. Lakeman was formerly with the American Society for the Control of Cancer and the New York State Department of Health, both of which initiated some of the earliest health talks by radio. For publications on radio and information about the Council write to 60 East 42d St., New York.

Three years ago the Special Maternal Care Committee of the National Council of Women of Canada urged local units of the Council to organize for action. One result is reported in *Social Welfare*, Toronto (June, 1931), in the study of conditions in Toronto and an intensive speaking campaign which reached its climax on "Mother's Day."

"Parent-Teacher Associations and The Family of Tomorrow," by N. W. Edson. *Journal of Social Hygiene*, 450 7th Ave., New York. May, 1931. The opportunity and some methods.

Study courses on the preschool child and on child training are offered by *Parents' Magazine*, 255 4th Ave., New York. Based on magazine articles, discussion outlines, debate topics, etc. *Information free*. Dr. B. C. Gruenberg is co-author of the preschool series.

"Toward Understanding Children," *University of Iowa Extension Bulletin*, Iowa City. Feb. 1, 1931. Interesting example of university coöperation with a state conference on child development

and parent education. 95 pp. *Price unknown*.

More than half of Kiwanis Clubs of the United States and Canada are in places of less than 10,000. Missoula, Mont., has Rotary, Lions and Kiwanis with a total membership of 220 of which 108 are Kiwanis. Missoula was one of four Kiwanis given awards in the annual "efficiency contest." Among the several score activities were included: advocated and assisted in forming a public health council; assisted in Red Cross Roll Call and Christmas Seal Sale; assisted in furnishing milk to underweight children in the public schools; secured a school dentist and paid \$158.00 toward his salary; investigated and advised employment of a public health nurse in the public schools; furnished glasses for needy children at a cost of \$70.00.

Have state departments or state associations worked out plans for co-operation with these clubs—satisfactory to the service club and economical for the health agency?

CAMPAIGNS

In the July JOURNAL under Diphtheria we quoted D. M. Griswold, M.D. (*Ill. Health Quarterly*, State Dept. of Public Health. Jan.-Mar., 1931), on the significance of "mass movements." Dr. Griswold has some questions as to the campaign as a method:

I feel, however, that campaigns on diphtheria prevention or tuberculosis examinations, etc., should be used only in the early days of a piece of work and should soon be discontinued. Campaigns depend too much upon emotionalism and such undesirable emotions as fear and dread for their success. We should, therefore, cease as soon as possible the idea of campaigns for doing things that we should do. We should eliminate all such wholesome emotions as fear and dread and replace them with such positive ideas as the desire for good health; the desire for sound teeth; the desire for immunity against all diseases as far as that is possible.

BOOKS AND REPORTS

Bacteriology—Especially Determinative Bacteriology—By Dr. K. B. Lehmann and Dr. R. O. Neumann. *English translation of the 7th completely revised German edition. Volume II—Part I. General Bacteriology. Part II. Special Bacteriology. Edited by Robert S. Breed, New York Agricultural Experiment Station, Geneva, N. Y. New York: Stechert (Alfred Hafner), 1931. Price, \$12.50 for 2 Vol.*

The work of Lehmann and Neumann has for many years been a standard text used in several countries. The present volume is translated from the 7th German edition. Needless to add, a work which has gone through so many editions has not only received the benefit of criticism, but has proved its value.

The preparation of the English edition has required more than 2 years and the original had brought the material up to February, 1927. It is evident therefore that some of the material cannot be regarded as entirely up-to-date. The object and character of the book, however, lessen the importance of this, though there are some serious omissions which we believe the editor would have done well to have supplied in footnotes, a typical example of which is found under "Methods of Cultivating the Tubercle Bacillus." Some 8,000 citations are given, mostly German, though a fair attempt has been made to include the work of bacteriologists in other countries.

The editor believes that the outstanding "value of this book lies in its systematic arrangement of our knowledge regarding the still too imperfectly known and numerous types of bacteria." In this we agree. He acknowledges the

impossibility of a satisfactory classification of bacteria, but expresses regret that Professor Lehmann shows a tendency to modify the rules of nomenclature. We believe that Professor Lehmann has the best of the argument on this point.

Including 3 appendixes, there are 827 pages of text, into which a vast amount of recorded knowledge has been condensed, with a good index of 39 pages. As stated in the preface, the book has been published with little expectation of financial returns. To the editor and his assistants, as well as to the firm which is responsible for this English translation, a debt of gratitude is due from all bacteriologists.

The printing and binding, which were done in Germany, are excellent, and there are very few errors. The work can be commended without reservation to bacteriologists. M. P. RAVENEL

Practical Clinical Psychiatry for Students and Practitioners—By Edward A. Strecker, M.D., and Franklin G. Ebaugh, M.D. (3d ed.) Philadelphia: Blakiston, 1931. Price, \$4.00.

In the third edition of this popular textbook there are many new illustrations, and a new chapter of 63 pages on "Some Practical Aspects of Child Guidance Problems" has been added. In general, the rest of the text shows no important changes from the second edition. The general manner of presentation of material is excellent. The giving of actual cases does much to give the student a better understanding of the subject.

Minor criticisms might be made of the presentation of certain topics. In dis-

cusssing mental deficiency we find the statement that a moron has an intelligence quotient of from 50 to 74 and a mental age of from 7 to 10 years, two ratings which are somewhat contradictory.

The book is undoubtedly one of the best texts on psychiatry which we have at the present time and should continue to have wide use. KARL M. BOWMAN

The Significance of Water-Borne Typhoid Fever Outbreaks, 1920-1930—By *Abel Wolman and A. E. Gorman*, with a Foreword by *Thomas Parran, Jr.* Baltimore: *Williams & Wilkins*, 1931. 82 pp. Price, \$2.00.

The present-day emphasis in the public health program on personal hygiene has tended to obscure not only the undisputed and far-reaching accomplishments of sanitation but also, and more important, it has in a measure obliterated the fact that we still have in many communities dangerous problems in water supply and sewage disposal. The solution of these through measures which have been proved time and again to be effective are fundamental prerequisites to any elaboration of community programs for child hygiene, infant welfare, and personal hygiene, which are today receiving such great attention. This analysis of the major causes of water-borne outbreaks of typhoid fever and dysentery and the chronological record of 240 outbreaks in the United States and Canada comes therefore as a timely warning and emphasizes the dangers to which we are still exposed.

The authors are to be particularly congratulated and thanked for the clarity of their dissertation in a field which has not been marked for the lucidity of its reports.

Some of the tables would be helped by footnotes explaining that the symbols classifying the outbreak are taken from the excellent outline in Table 4.

The record indicates 7 repetitions of

outbreaks in the same city, of which 4 were from the same cause (rather than 5 and 1 as stated by the authors in their conclusions). Of the 8 states reporting no outbreaks during the decade, 2 are southern, but it is interesting to note that, with the exception of Maryland, all 5 states in which repetition of outbreaks occurred are in the north (Indiana, New York, North Dakota and Wisconsin).

This should prove a valuable source book for teachers, engineers and health officers. HOMER N. CALVER

The Measurement of Nervous Habits in Normal Children—By *Willard C. Olson, Ph.D.* Minneapolis: *University of Minnesota Press*, 1929. 97 pp. Price, \$2.00.

Dr. Olson's book is a report of a study which he conducted at the Institute of Child Welfare at the University of Minnesota and in the Minneapolis public schools. In the preliminary study the children were observed in the schoolroom for the manifestation of oral, nasal, hirsutal, ocular, aural and genital habits.

Of all those under observation, oral habits correlated most highly with the total score. In the main study one point was given for one or more manifestations of an oral habit (thumb sucking, finger sucking, nail biting, protruding tongue) per each 5-minute period of observation. As the most reliable procedure was found to be twenty 5-minute observations of each child, a child's score might be any number from 0 to 20, with the higher scores the more undesirable. For the main body of the study 636 children were observed in grades 1 through 8 of a single elementary school.

The scores of oral habits were found to distribute themselves over a normal curve so that "Properly stated the question concerning a child is not, 'Is he nervous?' but 'How nervous is he?'"

Apparently age, grade location and degree of intelligence had little influence upon the amount of habit manifested by the individual child. A reliable sex difference was, however, indicated in favor of the boys.

Consideration was given to the incidence of nervous habits among children of the same family; the effect upon the child of association with persons of nervous habits, outside the family group; the influence of fatigue, nutritional status, and length of breastfeeding upon nervous habits, etc. While certain relationships are indicated statistically in all these instances it is as yet impossible to talk in terms of causation. Dr. Olson recognizes the variability and multiplicity of factors in human affairs and is consequently cautious in drawing his conclusions.

The study is valuable because it is an adaptation of what Dr. Olson calls the "natural history approach" to controlled methods of research; we may await with interest the results of his further investigations.

JEANETTE REGENSBURG

Medical Jurisprudence—By *Alfred W. Herzog, M.D.* Indianapolis: Bobbs-Merrill, 1931. 1051 pp. Price, \$15.00.

Books devoted to medical jurisprudence usually deal either solely with the legal aspects, or else with the medical, and only rarely with both. This may be because they are written either by lawyers or by physicians and seldom by anyone who combines these two professions.

This ponderous volume by the editor of the *Medico-Legal Journal* is both legal and medical. Some parts of it will be valuable to the physician in pointing out his legal rights and liabilities, while others will serve as useful information for the lawyer by giving him more or less scientific discourses on various phases of medicine.

Among the 56 chapters is a rather brief one entitled "Health and Sanitation Authorities," which presents principles based on numerous court decisions with reference to the creation and organization of health authorities, their powers and duties, and liability for expenses. This material would probably be of interest to a practising physician, but not of great value to a health official or to a lawyer involved in public health litigation.

The book contains an extensive table of cases, a good index, and a fair bibliography. The references would have been improved if all the cases had been dated, despite the labor which would have been involved. This volume will be found of value for reference by those interested in medico-legal problems, even though the discriminating reader may not agree with all that is said, or with the interpretation of some of the legal decisions cited.

JAMES A. TOBEY

International Studies on the Relation Between the Private and Official Practice of Medicine with Special Reference to the Prevention of Disease—Conducted for the *Milbank Memorial Fund* by Sir Arthur News-holme, K.C.B., M.D., F.R.C.P. Vol. I. *The Netherlands, Scandinavia, Germany, Austria, Switzerland.* Baltimore: Williams & Wilkins, 1931. 248 pp. Price, \$4.00.

The publication of a series of International Studies on Medical Practice in various countries is an event of very special interest. We are beginning at last in this country to emerge from adolescent self-satisfaction and to recognize that older nations have much to teach us, particularly in the field of social organization. We could have no better instructor than Sir Arthur News-holme, whose wide experience as Chief Medical Officer of the Local Government Board of Great Britain equipped

him admirably for a survey of the health problems in other lands.

In this, the first of three volumes, are many specific lessons which may prove of significance to us in the solution of similar problems. In the chapter on Holland we have an opportunity to observe extraordinary success in the development of private mutual medical organizations for the treatment of disease under a system of voluntary co-operation; and to note the effect of a properly organized midwifery program on the maternal death rate.

In Denmark we find a development of hospitalization of unique completeness and a voluntary system of sickness and invalidity insurance which, without compulsion, has secured as wide a coverage as is obtained under compulsion in Germany. Here also we have an experience of nearly a century and a half in the treatment of venereal diseases under government auspices.

Sweden was similarly a pioneer, and has ever since been a leader, in the field of vital statistics with a system of registration dating back to 1748.

Norway presents a picture of a highly developed local health organization in which the medical officer is the key to the entire medical work in each commune, and its insurance system in which the doctor is paid on a service rather than a per capita basis is an interesting contrast to the methods in many other countries.

Germany illustrates the advantages and disadvantages of an extensive compulsory insurance system and of a wide variety of only partially coördinated social welfare organizations. The history of unfortunate conflicts between the medical profession and the public is fairly and fully told in its bearing on collective versus individual bargaining between the insurance fund and the physician. The case of the physician against the German system is fully and adequately presented.

The chapter on Austria presents a somewhat better picture and shows the working of a program in which district physicians are on a salary basis which does not depend directly either on specific services rendered or on the number of persons served. There is also considerable freedom with regard to the consultation of physicians not members of the official staff. The arguments against this program are presented in a significant quotation from Dr. Georg Weinlaender.

Finally, in Switzerland we see conditions somewhat more like those of the United States with 25 small cantons enjoying more or less complete home rule, some of them having compulsory sickness insurance and others not.

More detailed analyses of certain of these European systems can be obtained from the studies of the League of Nations and the International Labor Bureau. For a general picture in brief compass nothing could be better than this volume. It is accurate, dispassionate and well balanced. It should be invaluable to all thoughtful students of this problem as opening up new vistas of international experience in a most important field. C.-E. A. WINSLOW

Psychology for Nurses—By Fred A. Moss, M.D., Ph.D. Boston: Houghton Mifflin, 1931. 273 pp. Price, \$2.50.

This book, instead of leading the reader through a maze of definitions and then through a dry discourse on the anatomy and physiology of the nervous system, plunges into the practical aspects of psychology as a nurse needs to know them in her contacts with her patients and coworkers. She learns how to analyze and understand her own attitudes and emotions in order to be able to understand those of her patients.

Part I deals with Psychology and its Place in Nursing. Under this are such topics as, Traits People Have in Com-

mon; Factors Influencing Behavior; Effects of Bodily Conditions on Behavior; and chapters on Mental Disorders and Psychology and Delinquency.

Part II deals with Individual Differences, with chapters discussing individual differences due to race, family, training, age, sex, and emotional outlets. The chapter on Differences Due to Race, especially as it touches the negro, race prejudices and race differences in achievement, is especially good.

Sociology and mental hygiene are linked up with psychology in a way to make them all vivid, vital, and practical. It is refreshing to have an author realize that in most nursing schools now the subjects taught are of college grade and the textbooks do not need to be couched in language and form that a seventh or eighth grader can understand.

But why limit this book to nurses alone? Everybody could read and study it with interest and profit. I recommend it unreservedly.

EVA F. MACDOUGALL

So Youth May Know—By Roy E.

Dickerson. New York: Association Press, 1931. 255 pp. Price, \$2.00.

This is one of the most satisfactory books on social hygiene for boys yet written. The author has combined authentic data with sound philosophy. He has avoided "wishy-washy" sentimentalism and fearsome sensationalism—those two most distasteful concomitants of many previous volumes in this field. His treatment of such subjects as prostitution, masturbation, syphilis, and gonococcus infection, is in keeping with the best modern thought. Above all, his emphasis on decency and cleanliness makes his effort a guide-book rather than a mere series of "don'ts."

To sum up, here is a short, readable book which we can safely recommend for reading by boys of from early teens on. The preface adds nothing of value.

RAY H. EVERETT

Military Preventive Medicine—By George C. Dunham, M.D. (2d ed.) Carlisle Barracks, Pa.: Medical Field Service School, 1931.

That a second edition of this book has been called for in less than a year speaks well for it. The new edition has been revised, brought up to date, and two chapters—one on the administrative features of physical examinations, and the other on vital statistics—have been added. Fifty-four additional illustrations have also been included.

The good impression made by the first edition has been strengthened. The book is more complete and more valuable than before.

M. P. RAVENEL

Health and Human Welfare—By William E. Burkard, Ph.D., Raymond L. Chambers, Ph.D., and Frederick W. Maroney, M.D. New York: Lyons and Carnahan, 1931. 532 pp. Price, \$1.40.

This is another addition to the rapidly growing list of health textbooks for secondary schools.

The book is prepared in the usual textbook style with large type and numerous simple illustrations. At the end of each chapter is a list of questions followed by a concise summary of the subjects discussed. It should be easy for teachers to use and will probably make health interesting to children. There are numerous chapters whose application must be made at home, such as "Care of the Baby," and "Care of the Sick." A special section is devoted to "Information for Parents," adapted from a pamphlet prepared and used by Dr. Maroney when he was director of health education in the Atlantic City Public Schools.

Frauds, quacks and patent medicines are given well deserved space, and the problems of adolescence are presented, in a chapter called "The Spring of Life," in a careful and pleasing manner

that should be easily understood and yet not offensive to anybody.

In reading this book one gets an impression of frequent unnecessary repetition and occasional misplaced emphasis. An example of the latter are 4½ pages of directions on how to clean the teeth and only passing comment here and there on the value of diet in building strong teeth. Certainly scurvy is no longer a health problem, yet 10 pages are devoted to it.

Evidently the authors are not advocates of pasteurized milk and the following statement will not get unanimous approval—"To safeguard infants from scurvy they should be given liberal quantities of raw milk, if possible." For this reason "certified milk is better than pasteurized milk although it is more expensive." Nothing is said about milk-borne epidemics or the part pasteurization has played in stopping and preventing them.

Although an effort has evidently been made to touch on all the subjects relating to public health, no mention is made of water purification or sewage disposal. Chapters on "The Romance of Sanitation" and "Health and Science Today" cannot be considered complete with such omissions. A diagram showing the decline in typhoid fever death rates is described as showing "some striking results of the rise of the preventive treatment (inoculations) against this disease." None of the other far more important causes are mentioned.

In a brief description of "ringworm" only the old fashioned kind is mentioned. Nothing is said about the much more serious fungus infection between the toes which is now spreading rapidly and attracting so much attention. Other errors are not serious but ought not to escape a careful editor.

Bacteria in the form of chains of dots are called "cocci." The "spirillin" is given as the kind of bacteria that causes cholera. We are informed that pas-

teurized milk is that which has been heated to 122°-125° for 20 to 30 minutes, but the correct temperature is given in another connection. No doubt such errors will be corrected in the next edition.

We also should like to call the authors' attention to the omission of the name of the American Public Health Association from the list of national health organizations and that of "other organizations from which health education materials may be obtained."

JOHN HALL

The Story of Health—By Hope Holway. New York: Harper, 1931. 150 pp. Price, \$1.25.

No person can rightfully claim to possess that desirable attribute known as a liberal education unless he is cognizant of the principles of hygiene and sanitation. No student should ever leave school without this fundamental knowledge, which may be acquired in part by the historical method, since tradition and experience are among the best of all teachers.

In this attractively printed little book, the wife of an eminent sanitary engineer has presented a concise and readable summary of the history of medicine and the development of modern public health, a story which Dr. Logan Clendenning recommends in a brief foreword as the first course of reading for the young person to take outside the regular school texts.

The book covers a comprehensive field in a succinct but interesting manner. More space than approximately 2 pages might, however, have been devoted to Pasteur, possibly at the expense of the rather lengthy description of magic and the disease dispelling charms and sorceries of ancient man. Although some of the more recent episodes in the conquest of disease are rather sketchily presented, this narrative should inspire interest in the more com-

plete stories as given in a number of recent books about "microbe hunters" and "riders of the plagues." For this purpose, a useful bibliography is appended. There is a good index and also there are many excellent illustrations by Elmer Hader.

Mrs. Holway's volume can be recommended as one of the best of the texts on the history of public health designed for schoolroom use.

JAMES A. TOBEY

Proceedings of Ninth Annual Water Works School, University of Kansas, Lawrence, February 11, 12, 13, 1931.

The proceedings of the ninth annual water works school covered a number of branches of the water works profession and allied professions. The subjects included were sources of water supply; water treatment including softening, filtration and sterilization; biological and bacteriological examinations and control; plant operation; distribution and financing. Related papers touched upon the subjects of design and operation of sewage treatment plants; induction motors; concrete admixtures; swimming pool sanitation; and accidents and causes.

A paper on mottled enamel of the teeth, by R. W. Kehr, was of particular interest in that it brought out the extent of this dental defect in the State of Kansas and its relationship to municipal water supplies. The percentage of school children with mottled teeth in the infected areas varies from a very high percentage for those starting use of the municipal supply at birth down to zero for those starting its use at the age of about 14. Contributing causes of mottled enamel appear to be sodium bicarbonate in the water or a combina-

tion of sodium bicarbonate and a low total hardness. More complete chemical analyses in further studies is essential.

VINCENT B. LAMOUREUX

Chemistry for Nurses—By Harry C. Biddle, A.M. Philadelphia: Davis, 1931. 322 pp. Price, \$2.75.

This book is the outgrowth of a lecture and laboratory course which the author gave over a period of years in several large Cleveland hospitals.

The National League of Nursing Education recommends a 45-hour course in chemistry as an essential minimum for the nurse's training period which the material in this text is designed to fit.

One cannot but be impressed with the orderly arrangement of the book. Part I deals with Inorganic Chemistry, Part II, with Organic Chemistry. At the beginning of each chapter are several short questions reviewing the previous day's lesson; this furnishes efficient repetition to assure permanence of learning. Then comes an outline of the day's lesson, followed by some practical questions to stimulate interest. There are review questions at the end of each chapter, followed by Topics for Oral or Written Reports and Suggestions for Posters, Charts or Exhibits. Each chapter ends with a manual for laboratory work with several blank pages added for personal notes.

In the long appendix practical aspects of vitamins, milk, blood, urine, antiseptics and disinfectants, etc., which the nurse needs to know, are taken up.

This text is really professional in that only such facts and principles as have a bearing upon the work which the student must face are taken up. The book is recommended very highly. Its only drawback is the sheen on the paper.

EVA F. MACDOUGALL

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Suffolk County, N. Y.—How a county health department in a 2 years' period has brought about the coördination of existing services, removed overlapping, and filled gaps in health machinery is described in this 1930 report. A generalized nursing service on a township basis has been established, and supervision of milk production on a county-wide basis has been provided. All licenses and permits such as those for milk, boarding homes for children, maternity homes and the others required by the public health law and sanitary code are issued after inspection by the County Board of Health.

A veterinary division, the first of its kind in the state, was established under the board of health. Bovine tuberculosis eradication has been completed in addition to extensive investigations of other diseases of animals. Camps are regularly inspected during their period of operation as to water and milk supplies, sewage and garbage disposal. All records with reference to the work of the department are maintained in the central office and are readily available for consultation or other information purposes.

This county of 169,463 population records an infant mortality rate of 52. The expenditures for the last fiscal year amounted to \$63,000.

Hartford, Conn.—On the basis of a population of 164,072, a resident death rate of 10.5, a tuberculosis rate of 70, a cancer rate of 103.6, and a heart disease rate of 234.6 are reported. An infant mortality rate of 62.8 is noted. There were no deaths from diphtheria. The milk supply is obtained from tuberculin tested cows and over 90 per cent is pasteurized.

The Visiting Nurse Association furnished bedside care, case supervision,

and follow-up work of tuberculosis under the general supervision of the Board of Health. A somewhat similar arrangement has been made for providing child hygiene nursing services. A study of the causes back of the deaths of infants under 1 year of age revealed that in 97 per cent of the deaths from prenatal causes, the mother had not had adequate prenatal care, and in 81 per cent of those from postnatal causes, there had been no medical or nursing supervision before the illness.

With the prenatal, postnatal, and child welfare services available at the clinics of the hospitals, the Hartford Dispensary, and the city, there are sufficient facilities for all mothers and babies not receiving adequate care from their private physicians. The difficulty seems to be in convincing a certain type of mother of the need of the service.

A survey of the Charity and Health Departments of the city resulted in recommendations for the consolidation of the isolation and municipal hospitals under management of a board of public welfare and for 3 additional full-time physicians for the board of health to head bureaus of communicable disease, tuberculosis, and child welfare.

The prevention of disease rather than the treatment of the sick is considered to be a proper function of the Board of Health, and the operation of the isolation hospital as a part of the municipal hospital under the welfare board instead of as a separate unit will present distinct advantages.

New Hampshire—Increasing demands from the public for the assistance of various departments of the State Board of Health are indicated in the 31st report for the period ending June 30, 1930. A steady increase in the number of samples of public and semi-public water supplies analyzed is noted. Progress is being made in the

elimination of lead pipes from water systems. The water supply problem presented by summer tourists and campers is growing. "Withal, it means that all such sources, and, indeed, all surface sources, should be chlorinated, as a safeguard."

Tuberculosis control work is conducted by the State Tuberculosis Association, which is financed by the sale of Christmas seals and by contributions. In 1928 there were 305 deaths from tuberculosis, all forms, as compared with 234 (185 pulmonary) in 1929. Much diphtheria immunization work is reported in many of the cities and towns, particularly in Claremont. The division of maternity, infancy, and child hygiene has developed, among other things, hygiene class work for the junior and senior girls in the high schools of the state. The course comprises 7 lectures followed by a written examination. If a mark of 85 is attained, a Certificate of Hygiene is given to the pupils from the State Board of Health. Community classes for adults and Little Mothers' classes for girls between the ages of 10 and 14 are conducted by staff nurses. Monthly health bulletins are widely distributed.

Shanghai, China—The 1930 public health department report of Shanghai consists of 82 pages, besides a table of contents at the front and an alphabetical index at the back which increase the usefulness of this interesting document. The foreign death rate was 18.15 and the Chinese death rate recorded was 16.42 per 1,000 population. Of the total deaths included in the foreign death rate, 63.3 per cent were among Asiatics other than Chinese, while 53.6 per cent of the whole were Japanese.

A somewhat heavy mortality was noted among both foreigners and Chinese from measles. An increased incidence of this disease is recorded every second year. Of the major dis-

eases, cholera and smallpox showed a comparatively slight incidence. A very large increase in the number of malaria cases was noted. In general administration, steady progress is noted in the organization and control of licensed food and other premises. Structural improvements in dairies as laid down by the 1924 milk commission were completed.

Educational opportunities are discussed and it is noted that the Senior Chinese Medical Officer in the Public Health Department proceeded to Liverpool under the Holt Scheme with a view to postgraduate study in tropical medicine and hygiene. Plans have been perfected for the voluntary registration of medical practitioners, dentists, and veterinary surgeons. The report contains many excellent graphs and statistical tables.

Cleveland, O.—Cleveland's 1930 health report opens with a service directory, followed by an index of statistical tables and subjects discussed. The death rate of 10.99 per 1,000 population is considerably lower than that of the preceding year, 12.29, when an increase in influenza and pneumonia as well as a clinic disaster unfavorably affected the rate. The incidence of communicable diseases was low in 1930, with the exception of a sharp outbreak of poliomyelitis which began late in the summer, reached a peak in late September and declined in the late autumn. Infant mortality has fallen from 85.9 in 1920 to 54.48 in 1930.

The number of cases of tuberculosis reported has not materially increased or decreased in recent years, but tuberculosis among colored persons has become an increasingly important problem. About 16 per cent of the cases reported and 37 per cent of the deaths are among colored persons, although this group represents only about 8 per cent of the total population. In the

administration of a tuberculosis program the control of contacts is recognized as an important factor. At the central office of the bureau of tuberculosis a master file of all contacts 18 years of age and under is maintained, and contains 13,578 cards, 7,466 of which are for children under 12 years of age. Reference is made to a recent survey of existing conditions pertaining to the prevention and control of tuberculosis in the city and county.

For administrative purposes the City of Cleveland has been divided into 8 health districts, shown on a map. District health stations serve as centers for the field work of public health nurses and also offer clinic service for child hygiene and tuberculosis control. A district physician is also assigned to each station in order to render medical care to the indigent sick. Medical care to convalescent or ambulatory cases, which have been previously attended in the home by district physicians, is provided for at the health stations to a limited extent. A branch office of the bureau of sanitation is maintained in one station.

The area supplying the city with milk extends to several points beyond the state of Ohio. Whenever inspection is carried on at points more than 150 miles distant from the city, the cost is borne by the shippers inspected. All milk is from tuberculin tested herds and 99 per cent is pasteurized.

Montclair, N. J.—The 1930 health audit of the town of Montclair opens with a photograph of new quarters in a separate health center building, where "We are now able better to house and control our different clinics, our nursing bureau, and other activities, and we wish to emphasize the fact that the department has been furnished with a strong weapon for the control of contagion in the town."

During the year, there was added a

director of nurses, whose function is not only to direct the activities of health department nurses, but to coördinate the nursing services of the private as well as public organizations. The work of the Visiting Nurse Service of the Montclair Red Cross (Public Health Nursing Bureau) was taken over under an agreement with the Community Chest that the service would be financed by that body provided direct supervision were given by the Department of Health.

Another activity instituted by the Health Officer was the Birthday Greeting Card, sent on the first birthday of all children born in Montclair. This educational plan aims to attract the attention of the parent to the necessity for abundance of sleep, fresh air and sunshine, together with preventive measures that can be taken to keep the child free from contagion. The card is printed in two colors, blue and pink, with an envelope to match. An infant mortality rate of 35.4 is reported.

Baltimore, Md.—In the 1930 report of the Baltimore Health Department, vital statistics rates for the past decade have been adjusted on the basis of the population figures of the last federal census. The 1930 population at mid-year was 806,607, of which 143,557 were colored. A death rate for the year of 13.9 is recorded, 12.7 for the white and 19.6 for the colored persons. Figures are presented to show that the greatest effect in the reduction of the number of cases and deaths from typhoid was produced by the purifying of the drinking water (1911-1914) and the pasteurization of milk (1918). A case rate of 16.36 and a death rate of 3.35 are reported for 1930.

A quotation from the Health Officer's report on the bureau of child welfare seems appropriate.

Since this bureau was established in 1919, its work has been shown to be more and more important, because of its taking advantage of

the opportunity of being the first agency to teach parents and expectant parents many important factors in care of children; their nutrition, immunization against disease (smallpox and diphtheria), and the removal of physical defects that might become factors in preventing proper development of the child.

We consider that the child in the preschool age (birth to and including the 5th year) is in a period of life when a great deal may be done to insure vigorous childhood. Indeed, our work begins before the child is born, by counteracting syphilitic infections and organic lesions in the expectant mother, so that a live, healthy child may be born.

We recognize that unusual care must be taken by us to avoid encroaching upon the private physician's domain and we exercise it. Physicians will be of great service to us and to the citizens if they themselves will provide the necessary proper instruction and care in these cases that will prove attractive to parents, because we are inclined to believe that such activity will bring them closer and closer to the people as proper instructors in public health work.

Sarawak, Borneo—Interesting photographs and charts characterize the 1930 health department report of Sarawak. Among the various charts and graphs on permanent display in the health office are an administrative map of Sarawak, indicating communications, facilities, and the like; working maps showing water supplies, trades, conservancy and latrines, dairies, abattoirs (regularly flagged and corrected by district inspectors); a mosquito spot-map displaying the result of two anopheline mosquito surveys; weekly birth and death chart with quarterly rates; annual infant mortality rates with Malay and Chinese components; a map of the whole Eastern Arena, comprising the quadrilateral figure between the points Port Said, South Africa, Japan, and New Zealand. On receipt of the weekly wireless broadcast from the League of Nations office at Singapore the infected ports are flagged and the danger points thus instantly recognizable.

A small public health museum is at-

tached to the health office and deals with child welfare, malaria, mosquitoes, rats, food supplies, building materials, scavenging, conservancy, disinfectants, poisonous animals, meteorology, and water supplies. The visitors to this museum during the year numbered 977; and, of these, 452 were Chinese, 386 Malays, 54 Dyaks, 32 Indians, and 38 Europeans.

West Riding of Yorkshire—The 23d annual report of the school medical officer of West Riding of Yorkshire states that the question of nutrition was the chief object of scrutiny during the year. The policy of providing milk midway through the morning was continued and the amount of milk, whether free or in return for payment, was considerably increased. No systematic inspection has been made of the number of persons falling below the poverty line, but the existence of unemployment insurance is believed to prevent the submergence of many families below that line. Some families keep above by extraordinary management, and others fall below for the opposite reason.

A complete examination includes the three statutory age groups—(1) entrants, (2) intermediates, and (3) leavers, together with (4) special cases and children for (5) re-inspection. All children wearing glasses come under notice, and myopic children with 5 dioptics or more correction are seen by the school oculist. An inspection of sanitary conveniences of the school, the playground, children doing physical exercises and the assembled school completes the observation. The "mass inspection" is said to be an excellent complement to the examination of individual children. Members of the staff are urged to confer with the head teacher before leaving the school after completing an inspection.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Fertility Rates East and West— Farm women are 50 per cent more fertile than city women in the east and 75 per cent more so in the west. Many interesting speculations are suggested in this paper.

BERRY, K. Differential Fertility According to the Geographic Areas in the United States. *Milbank Quart. Bull.*, 9, 3: 79 (July), 1931.

State Pneumonia Study—The details are given of a five-year plan to facilitate early and general use of concentrated serum, and to devise methods for the treatment and prevention of pneumonia in Massachusetts.

BIGELOW, G. H. The Serum Treatment of Pneumonia. *New England J. Med.*, 205, 5: 242 (July 30), 1931.

Health Examination Technic—Principles are set forth by which the general physical examination may be given sufficient accuracy to serve as a scientific instrument.

BRITTEN, R. H. The Physical Examination as an Instrument of Research. *Pub. Health Rep.*, 46, 29: 1671 (July 17), 1931.

Rural School Ventilation—Minor respiratory illnesses which show a marked climatic variability in incidence are also affected by over-heating or over-chilling of the rural school rooms studied.

COLE, R., *et al.* A Study of Rural School Ventilation in Cattaraugus County, New York. *Am. J. Hyg.*, 14, 1: 49 (July), 1931.

Nurses and Nutrition—An effort to simplify nutrition teaching so that each nurse may offer a constructive program when it is needed.

GRANT, E. O., and FISHER, R. W. A Nutrition Program in a Public Health Associa-

tion. *Pub. Health Nurse*, 23, 7: 326 (July), 1931.

Toxoid in Infancy—Successful experience with the prophylactic use of diphtheria toxoid is reported in a group of children from 4 days to 2 years of age.

GREENGARD, J. Diphtheria Toxoid (Diphtheria Anatoxin-Ramon) in Infancy. *J. A. M. A.*, 97, 4: 228 (July 25), 1931.

Minor Ailments in Industry—A British hygienist's summary of the importance of so-called inconsequential illnesses as reflected in industrial output is abstracted in this leading article in a newcomer in the field of industrial hygiene.

HAYLOCK, G. A. Minor Ailments and Production. *Indust. Health Digest*, 1, 3: 1 (July), 1931.

Tuberculosis Case-Finding—The opportunities for detecting cases of tuberculosis which are always before the public health nurse are pointed out in two separate articles on case-finding and its technic.

JACOBS, P. P., and HODGSON, N. H. Case-Finding in Tuberculosis. *Pub. Health Nurse*, 23, 7: 320 (July), 1931.

High-Fat Hot Weather Diets—The injurious effects of an experimental diet high in vegetable fats, which were most marked at 30° C., were not noted or were only slight in animals maintained at 20° C.

KLIGLER, I. J., *et al.* Studies on the Effect of Environmental Factors on the Animal Organism. *Am. J. Hyg.*, 14, 1: 38 (July), 1931.

All About Malaria—Mosquito breeding control, screening, and treat-

ment of patients are discussed in this inclusive symposium.

LEPRINCE, J., *et al.* Symposium on Malaria. South. M. J., 24, 5: 407 (May), 1931.

Syphilis Control—The proposed state-wide program includes full-time county and city health administration, laboratory service, free arsenicals, public treatment facilities competently directed, and educational measures. With such facilities eventual success may be anticipated.

PARRAN, T. The Eradication of Syphilis as a Practical Public Health Objective. J. A. M. A., 97, 2: 73 (July 11), 1931.

Communicable Disease Nursing—One of the goals of public health nursing should be the education of mothers to prevent the exposure of their children to the communicable diseases. How much effort can be spared to this end is discussed in this excellent paper.

REEVE, I. Communicable Disease Aspect of Public Health Nursing. Pub. Health Nurse, 23, 7: 307 (July), 1931.

Immunization Results—Clear cut indeed are the results of a 3½-year experience in the testing and immunization of contagious disease nurses against

diphtheria and scarlet fever. Toxoid proved a more potent prophylactic agent than toxin-antitoxin mixture, and ricinoleated scarlet fever antigen was found to be disappointing in its results.

RHOADS, P. S. Skin Tests and Immunization Against Scarlet Fever and Diphtheria. J. A. M. A., 97, 3: 153 (July 18), 1931.

Efficiency of Toxoid Immunization—Canadian experience is recorded in support of toxoid as the prophylactic agent of choice which can be given without reactions if susceptible children are excluded following the test.

ROSS, N. A., and MCKINNAN, N. E. The Efficiency of Toxoid in Controlling Diphtheria. Canad. Pub. Health J., 22, 7: 333 (July), 1931.

Nationality and Adult Death Rates—Will the change in the nationality of the predominating immigrants from Irish and German stocks, with high death rates in the late age periods, to the southern Europeans, with lower rates, affect the increasing adult American death rates? An answer is found in this study.

WINSLOW, C.-E. A., and WANG, P. L. The Relation Between Changes in Nationality Stock and Increasing Death Rates in Adult Life. Am. J. Hyg., 14, 1: 79 (July), 1931.

NEWS FROM THE FIELD

LEONARD WOOD MEMORIAL LEPROSY WORK

THE Board of Directors of the Leonard Wood Memorial announces at this time the completion of its fund for \$2,000,000. It takes this opportunity of expressing its sincere thanks to each of the 50,000 American citizens who by their contributions have made possible this great American Foundation. The Board further assures the American public that these funds are being disbursed in accordance with the terms of the gifts and with the counsel of scientists experienced in the field of leprosy. It ventures the opinion that the encouraging results in leprosy treatment and the international good will that have already ensued are but forecasts of even greater progress in these respects in the future, and for these reasons believes it not amiss to congratulate all those who by their generosity have seen fit to become partners in this great international enterprise."

"The Leonard Wood Memorial's program of activities is devoted to research, direct and indirect, in the treatment of leprosy. It comprises two main divisions. About one-half million dollars is to be spent for buildings, equipment, and roads in the Philippines; the balance as a semi-endowment to be expended, both principal and interest, over a period of approximately 15 years. . . . One of the most important single items in the Memorial's capital building program, and the largest, was the establishing of a complete new leprosarium at Cebu, on the island of Cebu, nearly 400 miles southeast of Manila. This institution was planned to care for

those suffering from leprosy in its earlier and milder stages."

. . . .

"Another item was to be the establishing of a new skin clinic. The Philippines, like other countries of the Orient, abound in skin diseases. In many instances these represent incipient leprosy. The splendid new white concrete skin clinic built at Cebu by the Memorial is proving a God-send to children with loathsome affections, and is resulting in the detection of many cases of leprosy, and at a stage where the arresting of the disease is almost a certainty." —*Leonard Wood Memorial Booklet*, Metropolitan Tower, New York.

AMERICAN SOCIETY OF CIVIL ENGINEERS

THE Board of Directors of the American Society of Civil Engineers has authorized the appointment of a Committee on Municipal Cleansing. It is proposed that the committee shall consist of 3 members of the American Society of Civil Engineers, but that there shall be added to it a representative also from each of the following: American Society of Mechanical Engineers, the American Medical Association, the American Public Health Association and the American Society of Municipal Engineers.

Dr. Henry F. Vaughan has been appointed to represent the American Public Health Association.

CINCINNATI HEALTH CENTER

AN unsolicited gift of \$10,000 made by the Western and Southern Life Insurance Company makes possible the expansion of its program at the Cincinnati Health Center by the Board of

Health. The money is to be used for the purchase of an X-ray machine and whatever accessories are required, as well as to defray the cost of the services of a part-time expert X-ray operator.

EUGENICS

THE Third International Congress of Eugenics will be held in New York, during the summer of 1932.

DRESDEN LOAN EXHIBIT AT LIFE EXTENSION INSTITUTE

AN unusual and interesting collection of graphic charts and anatomical specimens from the famous Museum of Hygiene of Dresden has been loaned by the Museum to the Life Extension Institute and is on exhibition at the Head Office in New York.

This world-renowned Dresden museum is devoted to the instruction of the general public in the conservation of health. In 1911 the First International Hygiene Exhibition was held in Dresden which proved to be so successful that its founders and sponsors coöperated in the establishment of the museum as a permanent institution. Since its organization it has attracted millions of people from all parts of the world and is the gathering place of hundreds of international scientific associations. The health and hygiene sections of the League of Nations meet here regularly. In its beautiful and spacious buildings it has assembled in a vivid and interesting manner everything that is of significance to the health of the people.

The anatomical specimens included in the loan exhibit to the institute have been prepared by a special process which renders them translucent, making possible complete visualization of the underlying vascular and bony structures. These specimens are creating particular interest.

The Institute cordially invites all who may be interested to call and view this unique exhibit.

TO OPEN HOSPITAL NEAR ARCTIC CIRCLE
BISHOP TURQUOTIL, a pioneer missionary in the north country who is known as the "Bishop of the Arctic," left Churchill, Man., in July with 4 nurses, members of the Grey Nuns, in his 25-foot motor boat on the hazardous trip along the rocky west coast of Hudson Bay to open a hospital at Chesterfield Inlet. This will be the farthest north hospital on this continent.

The hospital will serve the nomadic Eskimos and the hunters and prospectors that search for fur and gold on the fringe of the Arctic Circle. Education courses in hygiene will be given to the Eskimo children by the 4 sisters.

TREATMENT FOR BLIND CHILDREN WITH CONGENITAL SYPHILIS

AS a result of the examinations conducted by the Virginia State Health Department in the School for the Deaf and Blind, and the subsequent examinations conducted by Dr. J. E. Blaydes of Bluefield this year, many blind children have been placed under treatment for congenital syphilis. The Bureau of Venereal Diseases is providing the drugs and arranging with private physicians in communities wherein the children reside for administering the treatment.

CHILDREN'S ACCIDENTS

MORE than 18,000 children in the United States were killed by accidents in 1930, and a very large number were seriously injured. Yet these startling figures represented a considerable decrease in accidental deaths of children, especially those of school age, according to the supervisor of New York City's child-safety demonstration. He found that low intelligence, worry, weariness, day-dreaming, love of adventure, and rebellion against authority are among the mental causes of accidents, and he suggests that parents and teachers should take them into con-

sideration in the training of children.—
U. S. Children's Bureau, Washington,
D. C.

DR. PETER LECTURES AT CHINESE MEDICAL SCHOOLS

DR. W. W. PETER, F. A. P. H. A., has been lecturing in the Central University Medical School and at Nanking University, and has given a course in industrial hygiene in Shanghai conducted jointly by the Chinese National Health Administration and the Ministry of Industries, in a school for the training of factory inspectors for the various provinces and larger municipalities.

PARIS MEETING ON TUBERCULOSIS

THE annual meeting of the Council of the International Union against Tuberculosis, whose Chairman is Professor Frölich (Norway), was held in Paris July 9; delegates from 17 countries attended this meeting.

The scientific session was held at the Pasteur Institute, in the new tuberculosis laboratories which the members of the Council visited under the guidance of Professor Calmette.

The next Conference of the International Union will be held at The Hague from September 6 to 9, 1932.

NATIONAL SAFETY COUNCIL

AS the teaching of safety becomes more general, and the quality of the work improves, there is an increasing need for pooling experiences, and giving publicity to approved and effective methods. As a result the National Safety Council has organized a Child Education Section corresponding to the other sections of the Council dealing with industrial and public safety problems.

The first meeting of the Child Education Section will be held in connection with the Twentieth Annual Safety Con-

gress to be held in Chicago October 12-16.

HEALTH DEPARTMENT SURVEY

DR. JOSEPH W. MOUNTIN, member of the A. P. H. A., recently began a survey for the U. S. Public Health Service of the Baltimore City Health Department, at the request of Dr. Charles Hampson Jones, Commissioner of Health of Baltimore. It will include an attempt to define the boundaries between public health work and private medical practice; will cover sanitation, vital statistics, communicable disease control, child and maternal hygiene, industrial and mental hygiene, hospital facilities and activities of welfare agencies. He recently made surveys of the Health Departments of the State of Tennessee and the cities of Knoxville, Tenn., and Wilkes-Barre, Pa.

PERSONALS

DR. CLARENCE L. SCAMMAN, F.A.P.H.A., of Boston, formerly deputy commissioner of public health of Massachusetts and director of the division of communicable diseases, has become director of the division of public health of the Commonwealth Fund of New York.

DR. WALTER W. LEE, F.A.P.H.A., has been appointed District State Health Officer in the Berkshire district of Massachusetts, succeeding Dr. Frederick S. Leeder, who has a similar position in the Southern Berkshire Health District.

DR. E. H. PADDEN has been appointed Flight Surgeon for the three airways of the United Air Lines west of Chicago. These include Boeing Air Transport, between Chicago and San Francisco; Pacific Air Transport, between Seattle and San Diego; and Varney Air Lines, between Salt Lake City and Seattle.

DR. FREDERICK RAND ROGERS, Director of the Health and Physical Education Division of the University of the State of New York, will leave the department September 1 to become dean of student health and physical education at Boston University.

HUNTINGTON WILLIAMS, M.D., D.P.H., of the New York State Department of Health, Life Member of the American Public Health Association, has been appointed Director of Health of Baltimore, Md., by Mayor Howard W. Jackson of Baltimore.

RECENT APPOINTMENTS in Kentucky include: Dr. Lewis C. Coleman, of Salyersville, to Madison County, succeeding Dr. Harold W. Sterling, who has accepted an appointment in the U. S. Public Health Service; Dr. Robert J. Gillespie, of Long Beach, Miss., to Magoffin County, succeeding Dr. Lewis C. Coleman; Dr. Allen F. Murphy, of Beckley, W. Va., to Lee County; Dr. Squire R. Boggess, of Lawrenceburg, to Anderson County.

DR. JAMES M. PARROTT, of Kinston, N. C., was appointed secretary of the Board of Health and State Health Officer, succeeding the late Dr. Charles O'H. Laughinghouse.

DR. WILLIAM O. McDERMOTT, of Casper, Wyo., was recently appointed Health Officer of Natrona County, succeeding Dr. Homer R. Lathrop.

DR. FRANCES M. LANE, of Cody, Wyo., was recently named Health Officer of Park County, replacing Dr. Frank A. Mills, of Powell, Wyo.

DR. ADELAIDE BROWN, F.A.P.H.A., of San Francisco, has resigned from her office in the California State Board of Health, with which she was connected for over ten years.

ELLSWORTH L. FILBY, F.A.P.H.A., has resigned as Chief Engineer and Director of the Bureau of Engineering, Florida State Board of Health, to become a member of the staff of Black

& Veatch, Consulting Engineers of Kansas City, Mo.

CONFERENCES

September 14-17, Sixtieth Annual Meeting, American Public Health Association, Montreal, Canada.

September 20-26, First National Congress on Social Service for Children in Argentina, under the auspices of the National Council of Women of Argentina, Buenos Aires, Argentina.

September 20-26, Medical Association of South Africa, Johannesburg, South Africa.

September 23-30, Centenary Meeting of the British Association for the Advancement of Science, London.

September 25-28, American Protestant Hospital Association, Toronto, Ont.

September 28, Children's Hospital Association, Toronto, Ont.

September 28-October 2, American Hospital Association, Toronto, Ont.

September 28-October 2, American Occupational Therapy Association, Toronto, Ont.

October 12-16, Twentieth Annual Safety Congress, Chicago, Ill.

October 19, 20, Conference of the Child Study Association, New York, N. Y.

October 22, 23, Seventh Annual Meeting of the Missouri Water and Sewerage Conference, Jefferson City, Mo.

November 9-14, the Ninth Texas Sanitarians' Short School, Houston, Tex.

July, 1932, The Second International Conference of Social Work, Frankfurt, Germany.

Training for the Public Health Engineer*

S. C. PRESCOTT, F. A. P. H. A.

Massachusetts Institute of Technology, Cambridge, Mass.

A HUNDRED years ago there were but two types of engineers—"military" engineers, whose activities were concerned with operations of warfare and defense, and "civil" engineers who dealt primarily with the varied problems of civil life and of the industries which developed therefrom.

In contrast with such a simplicity of designation, we recognize that today there are many kinds or varieties of engineers, some of highly specialized training and restricted to a narrow field of professional activity, others concerned with broader and more general aspects of present-day problems. One fact stands out boldly to characterize the work of all these men and to define their status as a group: *They are all dealing in some manner with the materials, forces or phenomena of nature, and utilizing or controlling them for the advancement of the interests of man.* Thus we may define the function of the engineer in a broad sense.

The great differentiation mentioned has obviously come about as a result of the rapid growth or extension of scientific knowledge, and the practical detailed application of the facts and principles of science to the methods and manifold procedures of production, manufacture, transportation, communication, illumination, and other agencies of modification or control of environmental conditions, which tend to add to the welfare, convenience, and comfort of mankind. In this diversity of specialized pursuits which has thus been made possible, we now recognize public health engineering as an essential calling, the prime

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 17, 1931.

object of which is to control the factors of the physical environment as they especially affect the health and welfare of aggregates of people, whether in small groups, or in cities, states or special areas, or in the nation as a whole.

In order to illustrate more definitely what is meant by the "factors of the physical environment" in the relations specified, let me group the types of problems which may be encountered, and thus indicate in some degree the breadth of preliminary engineering and biological knowledge which this type of engineer should be able to apply in their solution.

1. Water pollution and water supply, comprising methods of analysis and measurement, preliminary investigations of treatment and purification of public water supplies, investigation of streams and harbors pollution, etc.
2. Development of methods of treatment and safe disposal of sewage and other fluid wastes of urban communities and of industrial plants
3. Refuse collection and disposal including possible utilization of by-products
4. The control of insects and vermin—including drainage and reclamation of marshy districts infested by mosquitoes or other pests; fly control, rodent control, etc.
5. Ventilation and air hygiene—including dusts, odors, and gases
6. Special problems of housing and town planning, including congestion, street cleaning, and smoke and noise nuisances
7. Sanitary production, transportation, handling and control of city milk, shellfish, and other food supplies
8. Industrial hygiene and special health hazards in trades and industries
9. Sanitation of playgrounds and swimming pools, bathing beaches, tourist camps, roadside stands, etc.
10. The general problems of public health administration and organization, and coördination with the more specific aspects of epidemiology, infection and immunity and communicable disease control

It will, I believe, be readily recognized that each of the foregoing types of problems demands for its solution comprehension and accurate knowledge of the causative agents of disease and of factors in personal health, and at the same time gives opportunity for the application of engineering knowledge and principles. However, it will be noted that I have not emphasized problems incident to the final design and *construction* of great installations for metropolitan water supplies, or sewage disposal works, since I believe this comes properly within the field of activity of the civil or sanitary engineer. Obviously, the training of the public health engineer should not neglect serious work in this field; in fact, he should have a solid grounding in it on which he can safely expand and develop if he so desires. But I have intended to empha-

size the problems in which the engineering procedures incident to their solution are intimately related to or dependent upon the proper application of basic principles of bacteriology, chemistry, and sanitary science and of personal hygiene. This point of view seems to be in line with the position taken by the Sub-committee on Nomenclature, appointed (in December, 1930) by and reporting to the Committee on Training and Personnel of this Association which has set up a definition of the Public Health Engineer in the following terms:

A public health engineer is a graduate of a reputable engineering school, college, or university, who has received substantial training in the sanitation of the environment. Satisfactory training in this professional field (either undergraduate or through graduate study) includes such instruction in the fields of sanitary engineering, chemistry, bacteriology, biology and administrative methods, as is necessary to provide a thorough knowledge of the theory and practice of water purification, waste disposal, milk and food control, the destruction of the vectors of infection, and the conduct of health department activities in the field of sanitation.

The same report defines a sanitary engineer as

... a graduate of a recognized engineering school who is skilled in the design, construction and operation of water and sewage purification plants and in the conduct of engineering activities relating to the public health.

It is obvious that any general definition of a special professional field is subject to minor criticism or to differences in interpretation by those whose chief activities lie within the broad zone that is indicated in the inclusive phrase "activities relating to public health," but I think there will be little doubt as to the general soundness of the differentiation which has been suggested. A study of courses in sanitary engineering given at those educational institutions which have offered them, shows that in most or all cases they have been largely modified courses in civil engineering, with a relatively small amount of time given to the broad aspects of public health problems aside from water and sewage.

The contribution which engineering has made to public health work in the past 50 years is to my mind one of the strongest arguments for a more broadly conceived basis for coöperation. In this period, the medical man, the sanitary bacteriologist, and the engineer have worked together for the control of certain types of communicable diseases. The result has been the remarkable conquest of water-borne diseases, which, while not complete, is extensive enough to provide the evidence that it is quite within the power of man to reduce them to comparative insignificance, if not entirely to eradicate them. Today in America, cholera is unknown, typhoid fever and dysentery are very greatly re-

duced and declining constantly. This has been largely due to purification and careful control of water supplies and to extension and improvement of sewerage facilities and the development of methods of treating sewage and preventing direct contamination from excreta.

The lowering of the death rate from communicable diseases in general has been due to numerous factors, but to a great extent it has been the result of the securing and maintenance of a better environment through the application of public health engineering. The results which have already been obtained indicate clearly to my mind the desirability of a specialized training in which the principles of chemistry, biology, and bacteriology, and of engineering procedures are combined and coördinated in a logical and consecutive manner and with one common objective. The student who successfully undertakes such a course of discipline may then, I believe, enter upon his professional work equipped to understand and appreciate the character and the magnitude of the problems he is likely to encounter, and to study analytically, in the light of the principles he has learned, the method of attack which is likely to be effective. In other words, he can visualize his problem as a whole, and apply the facts of science to its solution. This may not be as simple as it sounds. Many public health problems are of complex character, involving physical, chemical, and biological phenomena, and necessitating for their solution not only an extensive knowledge of fundamental facts and principles, but a delicacy of judgment and comprehension which is likely to be obtained only by experience.

It is manifestly impossible in the scholastic training of the embryo public health engineer, to provision for him all the situations which he will encounter in actual practice, or even many of them. But it seems to be possible so to impress on him the fundamental principles which are the tools he must constantly use that he can approach his work with a background of scientific fact and intelligence, and confidence in the accuracy of his reasoning as to procedures which must be or may be employed. This should develop in him the ability to translate all the problems or tasks to which he is early assigned into what will become his working capital of public health engineering vision and experience.

We may now inquire more specifically regarding the fundamental and technical training for the student who wishes to become a public health engineer, and which will meet the requirements of the definition which has been suggested.

I wish to present for discussion the program which we have worked out at Massachusetts Institute of Technology. This is a course of 4 years in which, in addition to the regular academic sessions, a con-

siderable part of one summer is used for required work. Our course is planned in accordance with our accepted policy at Technology that the first 2 years' work should be of general and fundamental character, while the upper 2 years are devoted largely to subjects which bear more directly on professional attainment. It is also a part of our accepted policy that every engineering or scientific student should have, as a part of his curriculum, required work in English and modern languages, economics, and some informative or cultural courses outside his professional field.

It is obvious that for any student who hopes to gain prominence or effectiveness in science or engineering there must be a solid foundation of mathematics, physics and general chemistry. The student in public health engineering, therefore, has 2 years of calculus and differential equations, 2 years of physics, of which 1 is devoted to theoretical mechanics and 1 to the principles of electricity, optics and heat; a year of general chemistry and another of analytical chemistry. In these years also he received instruction in English, mechanical drawing, and descriptive geometry. The work of the first 2 years is therefore made up largely of subjects which aid in developing straight thinking, analytical reasoning, and the establishment of fundamental scientific principles and methods of expression.

In the second year the student has a broad introductory course in biology, in which, as in the other courses, fundamental principles are emphasized. Applied kinematics follows and further stresses the rigorous course in general and theoretical mechanics.

During the summer following the second year an intensive course of 6 weeks' duration is given in general, topographic and hydrographic surveying, as is a course in limnological field work in which the chemistry, physics, and biology of lakes and streams is presented. Studies on dissolved oxygen, carbon dioxide, temperature and alkalinity measurement, sampling and sanitary surveys, and the microscopic flora and fauna of the waters are among the matters taken up.

The student should now be prepared to enter upon the more specialized subjects on which public health engineering is based. On the public health side these include general bacteriology (considered both from health and engineering aspects); and infection and immunity, bacteriology of water, sewage, and foods, and municipal sanitation; on the purely engineering side, earthwork engineering, hydraulics, structures and strength of materials; in chemistry, organic chemistry, sanitary chemistry and the special methods of analysis of water and sewage. General studies and economics provide subjects of broadening influence or semi-technical significance.

The fourth year program continues the emphasis on public health

and engineering studies. Of the former, we include public health administration, vital and sanitary statistical methods, and a broad course designated as "sanitation" treats of the varied types and aspects of the special public health procedures (which I presented in the early part of this paper) which are not taken up elsewhere. Special emphasis is given to the subjects of drainage, insect control, the problems of milk supply sanitation, pasteurization processes and engineering, etc.; and the sanitary and engineering aspects of refuse and waste disposal, and to those aspects of food production and handling which involve not only a knowledge of bacteriological methods of examination but also may require distinctly engineering treatment.

While not ordinarily regarded as within the purview of the engineer, we believe that it is quite desirable for the public health engineer of the future should have some familiarity with the new processes of food technology which are making such rapid strides. A well organized course in industrial hygiene brings to the student the relations of factory processes and conditions and the health of the worker, and provides a direct avenue toward safety engineering and industrial health and personnel administration. Throughout the year a weekly biological colloquium makes possible practice in the art of preparing and delivering reports and papers of technical character.

On the engineering side, the work in structures is continued and is accompanied by correlated courses in sanitary design, and in hydraulic and sanitary engineering, in which the student is required to make the plans, calculations, and assembled drawings for some type of sanitary construction such as a sewer system, a water filtration or treatment plant, and some other more specialized type of installation of public health significance.

There is required also a course in the mechanical equipment of buildings which includes the consideration of heating, ventilating and humidifying equipment, lighting, plumbing and the other mechanical installations which are essential to the modern factory or business structure. Finally, a considerable portion of the last term of the undergraduate course is devoted to an original investigation of some problem involving bacteriological, administrative, statistical, or structural features which must be worked out by the student himself.

The accompanying program of the course shows the sequence of subjects during the 4 years, and the unit values of the courses presented. Summarized by general subject groupings, we have the following approximate allocation of time required in class work and preparation during the 4 years leading to the degree of Bachelor of Science in Public Health Engineering.

REQUIREMENTS FOR B.S. IN PUBLIC HEALTH ENGINEERING

TOTAL HOURS REQUIRED—6,060

	Hours	Per cent
Mechanical Drawing & Descriptive Geometry	180	3 approx
Military Science and Physical Training	240	4 "
Mathematics	480	8 "
Physics	660	11 "
Chemistry	915	15 "
English, Economics and General Studies	870	14 "
Biology and Public Health	1185	20 "
Engineering Studies	1530	25 "

It will be seen from the above arrangement that approximately 55 per cent of the time of the student is devoted to what may be regarded as general, fundamental, or cultural studies, and that these include subjects which are calculated to develop his accuracy and power of analytical thought as well as to give him the broad basis of general knowledge and human interest which must be a part of every educated man and which is especially demanded of the engineer whose future is to be devoted especially to problems of social and community significance.

We believe also that the suggested program is sound from the professional standpoint and supplies an adequate foundation on which a man may build his career and from which he may enter the administrative, the structural, or the consulting field, depending upon his natural aptitudes, ambitions, and opportunities.

BIOLOGY AND PUBLIC HEALTH

OPTION 3. PUBLIC HEALTH ENGINEERING

FIRST YEAR—SAME FOR ALL STUDENTS

Second Year

First Term	Hours per Week	Second Term	Hours per Week
Qualitative Analysis	7-2	Applied Mechanics	3-5
Biology, General	5-2	Quantitative Analysis	7-2

New Plan Sought for Transporting Malaria Cultures

AN improved method for transporting malaria cultures for treatment of victims of paresis (general paralysis of the insane) is being sought at the new U. S. Public Health Service investigation station at Columbia, S. C.

At present, the only certain way of transporting the infection is by live mosquitoes, which must be accompanied by attendants.

The work is being done at the State Hospital for the Insane, which was selected as the place for cultivation of these mosquitoes for distribution throughout the United States.

A great deal of the present expense in distributing malarial infections for paresis treatments would be eliminated, however, if a way could be found to ship only the live malaria cultures.

Laboratory facilities, which were obtained through the coöperation of Dr. C. F. Williams, Superintendent of the State Hospital, are ideal for the work now being carried on. The location is near a malarial district, where the "anopheles larva," the young malarial mosquito, is captured in the water.

Also, after the mosquitoes are hatched in the laboratory, it is not difficult to obtain malarial patients who will allow the mosquitoes to contract the infection from them.

Dr. James A. Hayne, State Health Officer of South Carolina, and his coworkers are helping the Service in this work.—*U. S. Daily*, Aug. 26, 1931.

Training of Health Department Personnel*

JOHN A. FERRELL, M. D., DR. P. H., F. A. P. H. A.

*Associate Director, The Rockefeller Foundation, International Health Division,
New York, N. Y.*

THE personnel requirements of health departments vary with their character, function, and size. State health departments as a rule are composed of functional divisions, each having a staff of specialists who should be qualified to supply expert consultant service to the state health officer and also to local health officers and their associates who compose the field staffs of town and county health departments. The state departments and their divisions usually do not undertake to supply health service directly in the home, the school, or the clinic, except when their aid is requested by the local health departments.

The customary divisions of the state department are: administration, laboratory procedures, epidemiology, vital statistics, sanitary engineering, and public health nursing. Some state health departments include also divisions for special diseases, such as tuberculosis, venereal diseases, cancer; divisions for special varieties of hygiene, such as maternal, infant, preschool, school, adult, oral, mental, or industrial hygiene; and divisions for special fields, such as food and drugs, inspection of state institutions, etc. Specialists are employed for service in the various divisions—one or more in each. Thus the training requirements for state health personnel are technical and varied. The specialist type of personnel predominates.

Local health departments of towns and counties are mainly engaged in supplying the people with information and service regarding health and the prevention and control of disease. The service is carried directly to homes, schools, and clinics. The staffs are composed mainly of medical officers of health, public health nurses, and sanitary inspectors. These emissaries of health interpret scientific knowledge to the masses. They are the teachers in the public health field. They should be broadly trained in public health subjects, and each should possess special training for his or her branch of service; but they are not expected to be technical experts to the degree that is

* Read before the Western Branch, American Public Health Association, at its Second Annual Meeting in Seattle, Wash., May 30, 1931.

essential for the specialist in the functional divisions of state health departments. The town and county health departments usually have limited resources. They are engaged in community, school, and home service. They rely usually upon the state health department personnel when problems arise requiring the aid and guidance of the technical expert. With few exceptions, the technical expert is not an employee of the town and county health departments. The chief requirement for personnel of these departments is for the field worker to carry on routine health measures.

Until recently the impression prevailed generally that any physician, or graduate bedside nurse, was qualified for local health work. In responsible circles, this is now known to be wrong. Public health service is itself a specialty, for which specific knowledge and training are necessary. University schools have been established to supply such training, and some of them have access to facilities for supplementing the intramural instruction with practice and instruction in the field.

The health departments of large cities combine into one organization the group of specialists, who typify the state organization, and the field workers, who typify the town and county unit. The cities have wealth, large populations, large budgets, and complex problems. They have or should have the laboratory, statistical, communicable disease, engineering, and other special services, as do the state health departments; and also the school, home, clinical, and community services, as do county and town organizations. Their requirements call for workers of every type.

TRAINING THE TECHNICAL EXPERTS IN PUBLIC HEALTH

Universities in the United States, Canada, and other countries, are now offering courses of training for public health specialists. Excellent courses in sanitary engineering are given by a number of institutions, such as Massachusetts Institute of Technology, Harvard and Johns Hopkins Universities, and a few state universities. At least 16 institutions in the United States (most of them universities) are giving courses in public health nursing which the National Organization for Public Health Nursing approves. (Every Pacific Coast state university is on the list.) They are as follows:

Department of Hygiene, University of California, Berkeley, Calif.

School of Public Health Nursing, Simmons College, Boston, Mass.

University of Michigan, Ann Arbor, Mich.

Washington University, St. Louis, Mo.

Department of Public Health, University of Minnesota, Minneapolis, Minn.

Department of Nursing Education, Teachers College, Columbia University,
New York, N. Y.

School of Applied Social Sciences, Western Reserve University, Cleveland, O.

School of Social Work, University of Oregon, Portland, Ore.

Pennsylvania School of Social and Health Work, Philadelphia, Pa.

Department of Nursing Education, George Peabody College for Teachers,
Nashville, Tenn.

Richmond School of Social Work and Public Health, Richmond, Va.

College of Science, Department of Nursing, University of Washington, Seattle,
Wash.

Vanderbilt University, Nashville, Tenn.

Department of Nursing Education, Detroit City College, Detroit, Mich.

Department of Public Health Nursing, Syracuse University, Syracuse, N. Y.

Department of Social and Health Work, Fordham University, New York, N. Y.

Fifteen universities in Canada and the United States are listed in the report of the Committee on Training and Personnel of the American Public Health Association as having schools or courses in public health.¹ A few of the universities listed also have schools or courses in sanitary engineering and in public health nursing.

These schools of public health, certainly the larger and more heavily endowed ones, give courses suitable for the training of all, or certainly the majority, of the technical experts needed in city and state health departments. Epidemiology, bacteriology, immunology, vital statistics, sanitary chemistry, physiological, industrial, and other types of hygiene, and public health administration are among the courses offered. The situation generally with regard to the technical or specialized personnel is not bad. The majority of the appointees have taken special training for their work, but there are too many who have not. For example, the percentage of the vital statisticians who have had special training is small. Moreover, all too many divisions of communicable diseases are manned by physicians who have had no special training in epidemiology, or in diagnosing, clinically or by laboratory methods, the various communicable diseases.

In certain localities public health administration is unsatisfactory. The impression has been common that almost any doctor could qualify as a public health administrator, even though he had no special training or experience in the public health field. Some of the self-styled experts in the field of government administration contend that all branches of governmental service must be subject to political parties and changing administration; that health departments must have executive heads who will rise and fall with the administration; and that deputies and division heads may be continued, if it pleases the political head to retain them. It seems to me that professional administrative

leadership in deciding upon policies, principles, personnel, and procedures is vital, and any plan which fails to secure and retain such leadership weakens the health service.

Among our governmental institutions, our state universities stand out for quality and stability; and this is due, I believe, to a plan of organization which to a large degree frees them from political domination. The public health administrator should be classed with the specialists and should have general training in the various fields served, and also experience in city or county health organizations. It is not to be expected that the administrator will demand desirable qualifications for his appointees, if his own training is quite limited.

TRAINING PERSONNEL FOR LOCAL HEALTH SERVICE

As stated above, medical officers of health, public health nurses, and sanitary officers compose the staffs of health organizations of towns and counties, and constitute an important part of city health organizations. The schools of public health listed in Table I of the report¹ as a rule offer courses suitable for local health officers. Likewise, the schools of public health nursing offer courses suitable for the field nurse. It is my impression that there are no university courses offered for sanitary inspectors, with the possible exception of a course at the University of Tennessee at Knoxville. Information as to the number of local health officers and public health nurses who have taken university courses in public health is not available, but the percentage is extremely small.

In England, where public health work is much older than in this country, and where, in general, compensation and tenure of office are more attractive, qualifications have been established for field workers in public health, a reserve of candidates for positions is available, and the qualification standards are enforced. In our country the conditions of service have not been stabilized; there is no reserve of trained candidates for the positions; and the demand for workers has consistently exceeded the supply. Consequently, qualification standards based upon special training and successful experience have not been generally adopted, and, where adopted, have not been rigidly enforced. Although it is highly desirable that the appointees in local health positions should have had university training in public health, and most of the institutions listed are prepared to give suitable training, it has been impossible in the past to secure enough personnel that has had such training.

A few of the more progressive state health officers are encouraging and even aiding their capable young officers and nurses to take uni-

versity courses, and although they have been unable to rely on the universities to supply their personnel needs, they are at least endeavoring to get away from the old plan of depending almost solely on the school of experience. It is still the practice in a number of states to select physicians and graduate nurses without special training in public health and expect them gradually to become proficient. Although some of our most capable health workers have been developed by this method, it has in general been found wasteful and inefficient.

Although experience is invaluable and there is no real substitute for it, it should be supplemented by thorough university training. While ultimately it may be possible, as already seems to be the case in England, to enforce standards of training in filling vacancies in local health organizations, there will be a transitional period of several years from the school of experience to the university training stage, during which the state and city health departments will find it necessary to supply short, intensive courses of practical training to their new appointees. The situation has been recognized by some of the more progressive state health officers, and stations have been established where this type of training is provided and where the candidates are appraised for positions. The teaching staff is carefully selected and consists, as a rule, of a medical health officer, a public health nurse, and a sanitary engineer or sanitary inspector, all of whom have had special training in public health and usually would be regarded as eligible for a faculty status in university groups.

The plan of operation varies somewhat. All of the instruction and field practice may be given in connection with a highly organized county health department, or the lecture and demonstration work may be given in the state health department quarters, or at the university, and the field work in nearby local health departments. Customarily the technical staffs of the state health departments give some of the lectures and demonstrations. The training offered is intended to be elementary and practical and in no sense a substitute for university courses.

Training of this character has been available since 1922 in Alabama, 1927 in Mississippi, and 1928 in Michigan. It was also available in Ohio during the period 1927-1929, inclusive. In Tennessee 3-month courses for health officers have been offered 2 or 3 times a year since 1928, through the coöperation of the State Health Department, the Department of Preventive Medicine of Vanderbilt University Medical School at Nashville, and nearby local health departments. The Nashville station has been limited to training for medical health officers; and the one in Michigan to the training of health officers and

nurses; whereas the stations in Alabama, Mississippi, and Ohio have received health officers, nurses, and inspectors. The station established by the Missouri State Board of Health receives nurses only. The Los Angeles County Health Department has given courses of from 2 to 4 months' duration for sanitary inspectors.

Many of the persons admitted to these stations have, in the course of their training, been carefully appraised as to suitability for positions. A number have been found unsuited to public health work and have not been given appointments. Where training stations admit health officers, nurses, and inspectors to the training, the workers become acquainted with each other and learn something of the fields of activity for which each group is best qualified, and thus understanding and the spirit of team-play are developed. The state health officers who have employed persons trained at these stations have been well pleased with the results; the service in the various branches of the health departments has been more efficient than in the past; the taxpayers have been more favorably impressed than was the case when inexperienced and untested workers were employed; and the percentage of failures of health departments has been much lower.

A canvass as to the sources from which schools of public health derive their students indicates that health departments utilizing training stations are also the ones as a rule which are gradually having increased representatives among the students in the schools of public health. Experience tends to show that the training stations are complementary and supplementary to the schools of public health and that they are in no sense competitive. If in due course the schools of public health should turn out a sufficient number of trained workers to fill the vacancies in health departments, the training stations could be discontinued, but either the schools of public health or the state health departments will find it necessary to make permanent provision for practical training for appointees who have had school of public health training. Until college courses in public health are available for sanitary inspectors, the city and state health departments will find it necessary to provide practical training for them. The salaries available for these workers, like those for health officers and nurses, are generally so low that the incentive for taking extensive training is lacking. Until the condition improves, it will be necessary for health departments and coöperating voluntary health agencies to give financial assistance to health workers to take training, not only to those attending university courses in public health, but also to those taking short intensive instruction at training stations.

A few of the health departments have made a beginning in this

direction by allowing study leave with full or part pay during the period of training. School of public health courses cost from \$1,500 to more than \$2,000 per school year, whereas attendance at field training stations requires from \$3 to \$5 a day for meals and lodging and provision for travel. In general, it must be admitted that the situation with regard to the training of health department personnel is unsatisfactory, and that the public health executives and the health workers have not been sufficiently concerned.

Now that university courses are available for training technical experts, medical officers of health, and public health nurses; and no doubt before long will be available for sanitary inspectors; and that health workers, to an increasing degree, are recognizing the necessity for public health training; the outlook may be regarded as encouraging. Moreover, as a number of the more progressive health officers, finding themselves unable to secure university-trained personnel, are making provision for and demanding at least a few weeks of training and experience under competent instructors as a condition of appointment, rendering it unnecessary to accept workers with no training, the outlook is hopeful.

But the transition is needlessly slow. Health executives, health workers, legislators, and taxpayers should be educated as rapidly as possible concerning the need of employing only trained health personnel. Qualification standards for personnel cannot be rigidly enforced, however, until the supply of trained workers approximates the demand. No phase of public health work is more important than raising the eligibility standards for appointment, and this in turn will have to go hand in hand with placing public health work on a professional basis, reasonably free from political interference, and on a plane where compensation and security of tenure will compare favorably with the prevailing standards in other attractive professions.

SUMMARY

1. Health department personnel requirements call for technically trained experts, such as public health administrators, statisticians, epidemiologists, bacteriologists, immunologists, sanitary engineers, public health nurses, etc., for service in state and city health departments.
2. For town, county, and city health departments, health officers, public health nurses, and sanitary inspectors are required.
3. University courses in special schools or schools of public health are available for the training of technical experts and, as a rule, fair standards of training have been established. For local health service, the university schools of public health and public health nursing offer suitable courses for health officers and nurses, but not for sanitary inspectors.

4. The supply of local health workers furnished by the schools of public health is extremely small and so woefully inadequate that state health departments have been forced to develop training stations where intensive instruction and field experience can be given. These training stations are intended to serve only during a transitional period until the schools of public health can meet the demand in so far as scientific instruction is concerned. They may be needed permanently to supplement the university training by functioning as practise schools.

5. The situation with regard to trained personnel is steadily improving, but progress is needlessly slow; consequently the health authorities and others interested should take measures to stimulate more rapid development.

Milbank Memorial Fund

ACCORDING to the report of the twenty-sixth year of work of the Milbank Memorial Fund of New York, this institution appropriated a total sum of \$1,436,913.83 last year for distribution among 25 health and social welfare organizations, in addition to \$230,251.12 paid on grants of previous years. This represents an increase of \$680,913 over the Fund's appropriations in 1929. Pledges from income amounted to \$686,425.83, while a total of \$750,000 was appropriated from principal. Actual payments on these pledges in 1930, together with payments on grants of previous years, reached a total of \$1,098,059.95.

Since its foundation in 1905 by Mrs. Elizabeth Milbank Anderson, the Milbank Memorial Fund has expended \$7,506,900 in philanthropic work, chiefly through grants to 136 organizations in the fields of health, social welfare and education. The Fund's activities in recent years have been largely confined to public health education and administration, chiefly in connection with the New York Health Demonstrations carried on in Cattaraugus County, N. Y., Syracuse, N. Y., and the Bellevue-Yorkville section of the City of New York. The more noteworthy, therefore, were the organization's grants of \$607,250 during the past year for social welfare. They represent the largest commitments in this field which the foundation has ever made in one year, comparing with \$27,728.53 in 1929, and \$188,298.32 in 1920, the previous record year. Public health, it is recognized, is now so linked up with social and economic questions that it cannot very well be separated from these broader fields.

Sanitary Control of Shellfish in the State of Washington*

H. W. NIGHTINGALE

State Sanitary Engineer, State Department of Health, Seattle, Wash.

THE shellfish industry in the State of Washington is extensive since there are many sheltered bays and inlets in which cultivation can be successfully carried on, and wherein natural beds exist.

The shellfish of economic importance are oysters, clams and scallops. The oysters are of two distinct types, the small Olympia or native, and the large Pacific or Japanese, lately introduced through importation of seed from Japan. The clams are known as the razor, butter, and little neck varieties. The scallops are of a typical west coast species.

The marketable oysters are entirely of cultivated stock since the natural beds in this region, as elsewhere, have been depleted or have disappeared from other causes. The clams and scallops occur entirely in natural beds over a wide territory. All these shellfish are marketed in a fresh or raw state. Razor and butter clams as well as a few of the Pacific oysters are canned.

The oyster beds are in shallow bays and inlets usually close to the shore line. The practice of diking to avoid continual exposure at low tide is a feature not observed in eastern waters where the oyster beds are not usually exposed during such periods. The Pacific clam beds are on beaches along the shore line and not on detached flats as is often the case on the Atlantic coast. The scallops are found in relatively deep waters in the Puget Sound region.

There are 4 distinct oyster producing regions in this state, the Olympia area, an extensive network of inlets and bays, Hood Canal, Samish Bay and Willapa Bay. The clam beds are scattered over the same area as well as along the beaches of the Pacific Ocean.

During the year 1924 preliminary observations toward the sanitary control of shellfish in Washington were made by Dr. A. U. Simpson, Epidemiologist of the State Department of Health. In 1926, the

* Read before the Western Branch, American Public Health Association, at its Second Annual Meeting in Seattle, Wash., May 29, 1931.

Division of Sanitation of this department began an organized series of surveys of the sanitary condition surrounding the shellfish growing areas, culling houses, shucking and packing plants. In 1927 Rules and Regulations for the Sanitary Control of Shellfish were adopted by the State Board of Health. The department was materially assisted in initiating this control work by engineers of the U. S. Public Health Service, whose advice based upon experience in other states was of great value.

The Rules and Regulations governing the sanitary control of shellfish areas embody—boat sanitation, culling houses, examinations for employees and carriers, growing areas, sewage disposal, storage and cleansing, and pollution. The regulations covering shucking and packing plants relate to communicable diseases, equipment, operation, and construction. Regulations governing the handling and sale of shellfish subsequent to production and shipment deal with certification, records, shell and shucked stock as well as bulk shell stock.

The surveys and control work which have resulted in the certification of 43 shellfish companies and dealers approved by the State Department of Health and U. S. Public Health Service, have demonstrated that the sanitation of all phases of the shellfish industry is equally essential.

Owing to the fact that the population adjacent to the shellfish region is scattered and small, acute problems in the control of polluted areas have not yet arisen. Less than 0.1 per cent of the total shellfish producing area is subject to condemnation on account of uncontrolled pollution.

The problems of sanitary control have consequently been concerned with the sanitation of the shore line and contiguous areas which drain into the shellfish producing bays and inlets, as well as the control of population actually engaged in the shellfish industry.

Surveys have shown that houses along the shore line have been equipped with cesspools with the overflow passing onto the beach. In such instances septic tanks equipped with absorption areas or chemical toilets have been successfully used. In certain locations pit privies have sufficed, if properly situated, to prevent seepage into the bay or inlet. No fixed distance as on watersheds has been established for disposal equipment adjacent to salt water. Contamination reaching streams which enter the bays and inlets has been controlled in a similar manner.

During the preliminary surveys it was observed that the living quarters on the culling floats were equipped with primitive disposal systems of the dump privy type. Since oysters are usually held on

floats adjoining the living quarters for varying periods, it was not uncommon to observe fecal matter floating in the water within the float enclosure immediately in contact with the oysters. A number of cases of typhoid were traced directly to such conditions. It was therefore required that the culling floats be provided with chemical toilets. The problem of the disposal of the contents of these toilets when full was solved by locating them in most cases on a separate float, which could be detached from the culling house and towed down the bay for disposal during ebb tide. In a few instances where the culling houses were on the beach, disposal of the contents of the toilets by burial or earth absorption was feasible. Chemical toilets throughout the shellfish region have been satisfactorily installed and operated.

Sea water and shellfish samples have been periodically taken on the floats at the culling houses. Prior to the installation of chemical toilets and improvement in shore line sanitation, the scores of such samples ranged occasionally as high as 50. During the past 3 years shellfish and sea water scores within the oyster producing areas have ranged from 0 to 2, with the exception of one bay, in which an increase in the volume of raw sewage discharged from an adjacent town has rendered the oysters subject to periodic pollution, and therefore subject to withdrawal of certification. During the same period the oysters subject to sewage pollution deteriorated from other causes and consequently were not handled.

The domestic water supplies used by employees on the floats have also been checked and the employees examined for presence of typhoid carriers.

It has further been required that bath and laundry waste waters being discharged into tidal waters be treated for a period of 5 minutes with an effective sterilizing agent, equivalent to 3 p.p.m. of available chlorine.

Owing to the fact that small boats are used in transporting shellfish from culling houses to the shore, and since the distances covered by the boats are short, pails have been found to be adequate for excreta collection with provisions for its burial on shore above high tide lines.

Precautions against pollution of shellfish prior to shipment are taken by requiring strict control over removal of shellfish from polluted waters and relaying in clean and safe waters. During the past 2 years, permission has been granted under the department's supervision to remove about 600 sacks of oysters from a polluted area and to relay in a certified area with the restriction of holding the shellfish in this area for a period of at least 1 month before sale or shipment. The season during which the transfer took place was not the hiberna-

tion period. It is also necessary to prescribe that when shellfish are stored, floated, or cleansed, the water in which storage takes place must be of a standard of purity at least as high as that designated for growing areas.

During the early surveys many of the shucking and packing plants throughout the shellfish region were found to be insanitary and improperly designed.

The defects frequently observed were: inadequate lighting and ventilation, washing and packing room combined with shucking room, lack of floor drainage, shucking benches of material not permitting cleansing, no hot water or steam supply, lack of refrigeration, corroded and dented utensils, insanitary lavatory and sewage disposal facilities, and water supply of questionable purity.

Shortly after the Rules and Regulations concerning Sanitary Control of Shellfish were adopted, the majority of the shucking and packing plants were ready for certification. In 2 instances modern concrete plants were installed, which are model establishments.

Concrete shucking benches have been installed in most plants with entire success, since they can be readily cleansed. Monel metal utensils, though high in first cost, are used throughout most of the shucking and packing plants. These can be readily cleaned and do not deteriorate or chip as enamelled ware in constant service does.

In some of the smaller shucking plants kerosene burning sterilizers have been installed for the sterilization of utensils. In the large plants salmon retorts are used as sterilizers.

The shucked shellfish are cooled as soon as possible after shucking. For such refrigeration, outside containers are provided for ice, and no ice or other foreign substances are allowed in contact with shellfish. A temperature of 50° F. or below, but above freezing, is maintained in refrigerators where shucked shellfish are stored.

The shucked stock is packed in sealed cans, glass bottles and parchment containers. It is required that returnable shipping cans be cleaned and sterilized by steam prior to refilling, and that non-returnable cans be rinsed with hot water before filling.

It is required that no oysters, clams or scallops be sold or offered for sale in the State of Washington unless the shellfish shall have been produced and shipped in conformity with the regulations of the state in which they are grown and packed, and unless the shipment shall have been accompanied by tag, label, or other mark showing that the shipper has been duly certified by the state in which the plant is operated, such certification having been approved by the U. S. Public Health Service for shipments in interstate commerce.

In order to insure a safe product, all phases of the shellfish industry are subject to periodic inspection. New companies are organizing, especially in the Willapa Bay district, and new problems in the sanitary control of shellfish must inevitably arise since the industry is increasing in size. The industry as a whole has heartily coöperated with the State Department of Health by making the necessary improvements in the plants to conform to the Rules and Regulations on the Sanitary Control of Shellfish.

The Air Jet Hydrocyanic Acid Sprayer for Fumigation

A NEW method of using hydrocyanic acid as a fumigant is described in *Public Health Reports*. It has been shown that the methods in general use failed to destroy all rats and vermin, and there has been persistent recurrence on some ships in spite of fumigation, due to failure of the gases to penetrate into protected rat harborages. This is dependent upon the concentration of the fumigant to a certain extent. With the use of Zyklon, and other preparations of hydrocyanic acid in the solid form, the highest concentration is found in the hatchway near the bottom of the hold. All such materials require time for the evaporation of the gas so that the maximum concentration is not secured immediately.

At the New York Quarantine Station, liquid HCN is now used by the spray method, operated with a jet of compressed air. The apparatus is an adaptation of the oxyacetylene blowpipe. It is most effective when the HCN is supplied under a pressure of 75 to 100 lb., and the air from 100 to 200 lb. A smaller spray apparatus consisting of a heavy glass bottle supported by a heavy wire mesh has been devised for smaller compartments.

The great advantage of the new method is that the diffusion of the gas is uniform, maximum concentration being attained at once, and in the places where it is most needed. The disadvantage lies in the necessity of a compressed air apparatus or reservoir, which, however, can be easily installed in larger stations. For the present, at stations where the amount of fumigation done is small, it constitutes a real objection. Another danger lies in the transportation of liquid HCN.

The containers approved by the Interstate Commerce Commission are too heavy for ready handling on shipboard. The lighter containers for use on ships can be transported only by the quarantine boat. When fumigating boats are available, air compression apparatus may be installed as a part of the regular machinery. A record of the fumigations at New York with the spray apparatus shows a high degree of success.—C. L. Williams, Surgeon, U. S. Public Health Service, *Pub. Health Rep.*, July 24, 1931, p. 1755 (abstract).

Western State Boards of Health*

PLATT W. COVINGTON, M. D., F. A. P. H. A.

International Health Division, Rockefeller Foundation, Salt Lake City, Utah

IN the 17th and 18th centuries there were in this country no permanent organizations to promote public health. Upon the occurrence of an epidemic of proportions sufficient to cause widespread alarm, a committee, consisting largely of local physicians, was appointed to promulgate and enforce quarantine restrictions.

Louisiana† was the first state to establish by law a state board of health (1855). Its activities were largely confined to enforcing maritime quarantine regulations in an effort to prevent the importation of yellow fever. Fourteen years later, an eastern state, Massachusetts, established a board of health. This measure had been recommended 20 years previously by Samuel Shattuck, a layman, in the excellent report of his sanitary survey of public health conditions in the state. In Massachusetts the original activities of the state board of health were not confined to combating a single disease, as was the case in Louisiana, but were directed against all the diseases then considered preventable. The third state board of health was created by another western state, California (1870), just one year after the establishment of the Massachusetts board; then still another western state, Minnesota, followed suit; and, from that time on, every few years, other states formed boards of health. Washington created such a board in 1891.

At the present time, 4 western states, Idaho, New Mexico, Nebraska, and Oklahoma, do not have state boards of health or advisory public health councils, although one of them, Oklahoma, has a state health department. The other 3 have state public health bureaus within the state welfare departments. In the remaining 44 the state board of health supervises the state health department; it also formulates the policies of the state health department and has certain legislative authority in making rules and regulations for the protection of the health of the population.

The early conception of the duties of a state board of health was

* Read before the Western Branch, American Public Health Association, at its Second Annual Meeting in Seattle, Wash., May 30, 1931.

† For convenience of description, the 22 states west of the Mississippi River will be considered western states.

that it should investigate the cause of epidemics and give advice as to their prevention, especially to the legislature and local governmental bodies. For a long period many state boards of health continued to follow this program, refusing other responsibilities. The reason for this was, doubtless, the precedent established in Massachusetts. Combating epidemics was considered to be the sole duty of the sanitary authorities; scavenging, sewerage, and ventilation were the weapons invariably relied upon to destroy contagion. The theory of the spontaneous origin of disease through decaying vegetable and animal matter was then at the height of its popularity. With the development of bacteriology as a science, which followed upon the pioneer work of Pasteur, a vigorous campaign, in which Chapin, the father of modern public health procedure in this country, took a leading part, was instituted against these antiquated procedures and theories. But even in this more enlightened age, health officers frequently encounter persons whose opposition to modern public health procedures has as its origin the archaic beliefs and practices of the past.

Of the 22 states west of the Mississippi, which have an aggregate population of 37,369,967, or 30.4 per cent of our total population, 19 have areas larger than the 6 New England states. The governments of the western states are of much more recent origin than are those of the states east of the Mississippi. For instance, the average date of admission to statehood of the eastern states is 1804, and of the western states 1871, a difference of 67 years—more than a generation. The area of the 22 western states is $2\frac{1}{2}$ times greater than that of the 26 eastern states, 2,117,654 square miles against 856,060. Hence, with the comparatively small population, scattered over a vast area, the problems of the western state boards often differ from those in the East, and the cost of conducting health work is correspondingly greater.

The tax levy of the average western state is \$51,925,000 as compared with \$90,345,000 for the average eastern state, a difference of \$38,420,000 in favor of the eastern state. The income of the average eastern state is 43 per cent greater than that of the average western state. Therefore, it is not surprising that the most outstanding problem of western state health departments is that of securing from their legislatures appropriations approaching adequacy, the need of which may be better appreciated when it is realized that in 1930 the per capita cost of eastern state health departments was \$.15 as compared with \$.06 for the western states—60 per cent greater for the East than the West.

The average yearly salary of a western state health officer is \$4,527, that of an eastern state health officer, \$6,628—a difference of 32 per

cent in favor of the latter. Nor is the tenure of office in the West as secure as in the East. Of the 26 eastern states, the state health officers in 21 are appointed by a non-partisan board of health, whereas in the West this is the case in only 13 of the 22 states. In the West the state health officer is usually appointed by the governor, or by the governor with the consent of the senate. The states making the greatest progress in public health work are those in which the health officer's tenure of office is based upon efficiency.

In 34 states the term of office of the members of the state board of health expires in alternate, or in different years, so that at least part (usually a majority) of the board will always consist of men who are experienced in handling its affairs. Among the western states there are 13 such boards and among the eastern 21.

Within recent years there has been a noticeable trend toward the cabinet form of state government. The stimulation of sentiment for this has been due largely to the activities of individuals or agencies that specialize in reorganizing government services on an efficient basis. When such state governments are established, the state health officer is often made a member of the governor's cabinet and receives his appointment directly from the governor. Hence, the appointment becomes political and with each change in administration there is usually a change of state health officer. Such organizations have so far proved to be a detriment to state health work.

In 3 of the western states, the health department is a state public health bureau, maintained within the state welfare department. In 2 of these, Nebraska and Idaho, a layman who has had no previous training in health or welfare work is director of the state welfare department. In New Mexico, a state board of public welfare formulates the policies of the department. In addition to the public health bureau there are others within the state welfare department. In Idaho, according to the former director of the department, the public health activities amount to at least 98 per cent of the total activities of the state welfare department. Such a condition is unfortunate, inasmuch as the state's public health policies are formulated by a person insufficiently prepared for such responsibility. This, however, is not the case in New Mexico and Nebraska where a full-time medical director is in charge of the state public health bureau. On the staff of the Idaho State Welfare Department there is a part-time medical adviser.

The most significant of recent developments in state health work is the policy of giving state aid, financial and other, in providing efficient full-time local health service.

According to the reports of the U. S. Public Health Service the first

rural county within the United States to place its health work on a full-time basis was Yakima County, Wash. (July 1, 1911). This action established an important precedent which has since been followed by many counties throughout the United States as well as by similar geographical units in many foreign countries. Each year the number of county health units has shown a decided increase. On December 31, 1930, there were 534 rural counties in the United States maintaining full-time health departments. A number of the state health departments have stimulated the development of such local departments by securing from the state legislatures specific appropriations to be used in defraying part of the costs of their maintenance. Among the western states, 6 have such appropriations, and among the eastern, 10.

Table I shows the growth of full-time county health units over a 5-year period in both the eastern and western states. It is interesting to

TABLE I

Year	Eastern States		Western States	
	Number	Per Cent of Increase	Number	Per Cent of Increase
1925	219		85	11.7
1926	247	12.8	95	31.6
1927	293	18.6	125	12.8
1928	341	16.4	141	3.5
1929	383	12.3	146	8.9
1930	410	7.0	159	

note that during the 5-year period covered, the percentage of increase in county health units is the same in both groups.

In addition to state aid, a number of the county health units receive financial assistance from the U. S. Public Health Service and the International Health Division of the Rockefeller Foundation, and occasionally from other public health agencies that have adopted the policy of aiding in the development of full-time health service in rural areas.

The average annual budget for health units in rural counties is \$10,000. This amount ordinarily provides for a full-time staff consisting of 1 physician as health officer, 2 nurses, and 1 stenographer-clerk, or 1 nurse, 1 sanitary inspector, and 1 stenographer-clerk. The aid to the county is usually decreased following the demonstration of the value of the work, and when this occurs, the county's appropriation is correspondingly increased.

The legislatures of 4 of the western and 12 of the eastern states have enacted permissive county health unit laws legalizing the crea-

tion of full-time county health departments and permitting the incorporated towns within the county to consolidate their health work with that of the county. Most of these laws also permit the county to levy a specific tax for their maintenance.

Alabama has the largest number of full-time county health departments, 53 of its 67 counties maintaining such organizations; 88 per cent of its population is served by full-time health departments. Probably, within the next 4 years, there will be 1 or 2 states in which every county will have a full-time health department. Ohio, Maryland, and Arizona, in the order mentioned, are next in having the largest per cent of their rural population provided with full-time health service.

The problem of securing adequately trained personnel for such units, in the absence of which no unit should be organized, has proved to be greater than that of securing the necessary appropriations for their maintenance.

With the growth in efficient local health service there has been a tendency to decentralize the state health department, using the funds thus saved in aiding in the development of county health units. In the states in which the county health units are most numerous it is the opinion of public health authorities that the ideal state health department is one that maintains only the most essential bureaus, with a director in charge of each who is really an expert in his work, and, as such, can command the respect and confidence of the local health departments. Thus his advice and assistance to such departments are of great value. Needless to say, his scholastic and professional standing should be on a par with that of the departmental heads of our leading universities and colleges. This type of state health organization is the goal which many of the more progressive state health departments are striving to reach.

In such times as the present, with the financial depression so widespread, the demands on the state health departments have greatly increased. Seemingly this has not been appreciated by our appropriating bodies. In the states whose legislatures recently adjourned, only a few of the state health departments were provided with funds approaching adequacy; many have had their usual appropriations reduced; a few have received a small increase.

Studies on the Self-Disinfecting Power of the Skin*

JOHN F. NORTON, PH. D., F. A. P. H. A., AND
MARGUERITE F. NOVY

Department of Health, Detroit, Mich.

ARNOLD and his coworkers¹ have reported experiments from which they conclude that the skin possesses some inherent power to destroy bacteria. This disinfecting property was more marked with clean than with dirty skin. More recently similar experiments have been made with yeasts by Cornbleet and Montgomery.² In view of the importance of these conclusions from the standpoint of the spread of communicable disease and the influence of cleanliness as a factor in such spread, it seemed desirable to repeat the work.

The laboratory technic as described by Arnold, *et al.* was followed, *B. prodigiosus* being the test organism. Briefly, this consisted of immersing the hands in a dilute suspension of bacteria, gently rubbing a sterile cotton swab over a designated surface of the skin, inoculating an agar plate from the swab, incubating, and counting the colonies. Table I shows the results obtained, which coincide with those of Arnold. When the skin is rubbed with vaseline no such striking disappearance of bacteria is obtained. The experimental results were somewhat irregular but in general confirmed Arnold's findings. Similar results were obtained when the skin of the forearm was used instead of the hands, and the area inoculated by means of a gauze sponge which had been dipped in the bacterial suspension (Table II).

Since it is well known that viable bacteria exist in the skin, it seemed possible that some factors other than germicidal activity of the skin might account for the results. The technic was first investigated. It was found that in the streaking of the agar plates with the swab, some organisms were not removed. This is shown in Table III. After inoculating the agar surface, the swab was placed in a tube of broth and incubated over night. In a majority of instances the test organism, *B. prodigiosus*, was found. In some cases a skin organism, *Staphylococcus albus*, was present. These experiments were qualitative rather than quantitative and did not account for the observed de-

crease in bacteria. However, they served to show that the organisms were never entirely destroyed on the skin as might be concluded from

the agar plate counts. It was thought that the technic used gave comparable results.

During the experiments described it was observed that the surface of the skin usually became dry by the end of 10 minutes. Arnold and

his associates recognized the possible influence of this factor and reported that holding the hand in steam during the experiments did not change the results. Cornbleet and Montgomery also mention, but do not stress, the influence of moisture. Our experience is shown in Table IV. Similar results were obtained when the skin was kept moist by covering with wet gauze (Table V). This latter procedure is subject to some error because of the possible removal of bacteria by the gauze.

taken of the time at which the surface of the skin was apparently dry. The results are given in Table VI. The times required for disappearance of bacteria are not comparable with those recorded in Tables I, II, and III, since larger amounts of liquid were used to inoculate the skin. These results show that the large and striking drop in the number of bacteria recovered is without exception coincident with apparent dryness of the skin surface.

Another possible factor is the absorption of bacteria into the skin. An attempt was made to study this by removing a portion of skin from a cadaver, repeating the above experiments, and then examining stained sections of the skin. It was not possible to demonstrate the presence of bacteria in these sections.

If drying is the main factor causing the disappearance of bacteria from the surface of the skin, it should be possible to obtain the same results on other materials. This was done on glass slides, tanned hide (before and after washing), and filter paper. The results are recorded in Tables VII, VIII, and IX. The materials were kept at body temperature during the experiments. Again the apparent dryness of the surface was correlated with the disappearance of bacteria. Cotton swabs were also used, a number being immersed in the suspension at

the same time and a different swab used at each time interval. Bacteria remained viable on these swabs for longer periods than on filter paper or hide. The surface of a 5 per cent agar jelly was then tried, since such a surface would dry more slowly than that of filter paper.

The results are shown in Table X and are such as might be anticipated.

Filter paper was kept moist by placing it on the surface of an agar plate. A comparison of Tables XI and IX shows the effect of moisture. However, it was not possible to restore the viability of bacteria from the dried surface by moistening. This is true not only for inert ma-

In. = too many colonies to count.

terials but for the living skin as well. The technic was also tested by placing the filter paper in broth after rubbing with the swab. The test organism was found to be present uniformly even when no colonies appeared on the agar plate. Poured agar plate counts were also substituted for Arnold's technic. The pieces of filter paper were macerated in sterile water at the end of each time interval and plate counts made in the usual manner. The results are shown in Table XII. These results are not so striking as those of Table IX, but a relatively rapid death of organisms is indicated.

SUMMARY

Bacteria applied to the skin diminish in numbers very rapidly. This is particularly noticeable during the first 10 minutes. In the experiments reported, *B. prodigiosus* was used as the test organism.

Similar results are obtained with inert materials such as glass slides, filter paper, and tanned hide.

The most important factor involved appears to be moisture. Marked disappearance of organisms was coincident with apparent dryness of the surface. On surfaces kept moist bacteria remain viable for much longer periods than when the surfaces are allowed to dry.

These experiments fail to indicate any inherent germicidal power of living skin.

2. Cornbleet and Montgomery. *Arch. Derm. & Syph.*, 23: 908, 1931.

NOTE: Since these results were obtained, Arnold has suggested that if the time interval between inoculation of the skin and the agar plate is shortened, his phenomenon is more striking; this is being studied at the present time.

Report on 31 Strains of *B. dysenteriae* *Sonne* Isolated During an Epidemic in Rochester, N. Y.

ALICE D. LEAHY

*Bacteriological Laboratories, Strong Memorial and Rochester Municipal Hospitals,
Department of Bacteriology, University of Rochester, School of Medicine
and Dentistry, Rochester, N. Y.*

SINCE 1915, when Sonne¹ first described a late lactose fermenting bacillus as the causative agent of dysentery in Copenhagen, very few reports have been published in this country on the isolation of *B. dysenteriae Sonne* from either sporadic or epidemic dysentery. Gilbert and Coleman² in 1929 reported the occurrence of 12 cases of Sonne dysentery in New York State, and more recently Nelson³ in Boston, and Johnston and Brown⁴ in Toronto have published clinical and bacteriological data on this type of infection. Koser⁵ made a study of 19 strains from a wide variety of sources, and believes that a search for the organism might conceivably show it to be more frequent in the United States than was formerly supposed.

During the fall of 1930, there were encountered in Rochester, N. Y., 40 cases of dysentery of which 31, or 77.5 per cent, were due to the Sonne type of organism; 5, or 12.5 per cent, to the Flexner type; and 4, or 10 per cent, were undetermined. The strains isolated from these 4 cases were in all probability Sonne as they were not agglutinated by Flexner antiserum and only in the lower dilutions by polyvalent dysentery serum. Unfortunately they were not kept for further study.

Of the 31 cases due to *B. dysenteriae Sonne*, 27 occurred among children and 4 among adults. It is interesting to note in the cases of 23 children admitted to the Strong Memorial and Rochester Municipal Hospitals that a provisional diagnosis of dysentery was made in only 12, or a little more than 50 per cent. Poliomyelitis, encephalitis, tetanus, acute appendicitis and acute upper respiratory infection were some of the diagnoses. This is unlike the Flexner type of infection where the diagnosis of dysentery is easily made upon the appearance of blood and mucus in the stools. Blood does not appear in the stools of Sonne dysentery cases so early as in the Flexner, and neither is the diarrhea marked at the onset. The stools from the Sonne cases are usually green, watery, contain mucus, and may or may not contain

blood. In over 80 per cent of the cases, the first stools received for culture were positive for *B. dysenteriae* Sonne, but in a few instances it was necessary to obtain several specimens before the organism was isolated.

A cultural and serological study was made of these 31 strains of *B. dysenteriae* Sonne and they were compared with 6 known strains—5 received from the New York State Laboratory at Albany, and 1 (*B. ceylonensis* A)⁶ from Koser in Chicago. All of the strains were non-motile; produced no indol in 48 or 72 hours; did not liquefy gelatin in 14 days; reduced nitrates to nitrites, and formed acid without a clot in brom-cresol-purple milk.

In studying the fermentation reactions, 16 different carbohydrates were used and they were run in 2 series, the first set being sterilized by filtration and the second by autoclaving. There were no differences in reactions of the strains in the 2 series. All of the strains produced acid without gas in 24 hours in glucose, mannitol, maltose, 1-arabinose, levulose, galactose and rhamnose. No acid or gas was formed in 14 days in xylose, dulcitol, sorbitol, salicin, inositol and inulin. The fermentation of lactose, sucrose and raffinose was delayed. Lactose was fermented by all strains in from 2 to 14 days, the average time being 7 to 10 days.

Our strains did not acquire the ability to attack this sugar in a shorter time by growing on artificial mediums. All except 3 strains (Nos. 26, 32 and 34) when first isolated fermented sucrose in from 4 to 16 days, but after being subcultured repeatedly, only 11 strains produced acid in 2 weeks. Raffinose was fermented by all strains in from 4 to 9 days.

In Table I, the results of the serological tests are tabulated. For purposes of identification when the strains were first isolated, agglutination tests were made with a polyvalent dysentery serum and 2 monovalent Sonne serums (Nos. 1,621 and 261) sent to us from the New York State Laboratory at Albany. Eighteen to 24 hour cultures in 2 per cent peptone water or saline suspensions of agar slant cultures were used as antigens. With the polyvalent serum there were 12 strains which were not agglutinated; 1 strain was agglutinated in a dilution of 1-640; 5 in 1-320; 5 in 1-160; 3 in 1-80; 2 in 1-40 and 2 in 1-20. One strain was not tested when first isolated and was later lost. All of the known Sonne strains and the strain of *B. ceylonensis* A⁶ were agglutinated by the polyvalent serum.

In the case of the monovalent anti-Sonne serums, there were considerable variations, and in all cases where there was agglutination, the clumping was very fine. A hand lens was used to read the tests. The Sonne immune serum No. 1,621 agglutinated 15 strains out of 31.

Three of these (Nos. 15, 21 and 25) were not agglutinated by the anti-Sonne serum No. 261. This latter serum agglutinated 25 strains out of 28, there being an insufficient quantity of serum to test the last 3 strains isolated. Sixteen strains were agglutinated by No. 261 and not by No. 1,621; 8 strains were clumped by both serums. Strains Nos. 1, 4, and 8 were inagglutinable in either serum when peptone water cultures were used as antigens; but the saline suspensions were ag-

glutinated as shown in the table. The positive results obtained with serum No. 1,621 against strains Nos. 16, 18, and 19 were also with saline suspensions from agar slant cultures. In addition to giving a greater number of positive results, the saline suspensions produced much larger clumps, making the tests easier to read. The supply of these serums from the New York State Laboratory at Albany was insufficient to permit repeating all of the tests with saline suspensions in place of the peptone water cultures.

In view of the variability of these results, an attempt was made to produce other serums against some of the strains isolated in our laboratory. Two strains, Nos. 5 and 32, were selected as they agglutinated well by the Albany serums. Rabbits were inoculated intravenously first with heat-killed and later with living organisms. One of the animals died after the third injection, but the other survived and a serum was obtained which completely agglutinated the homologous strain in a dilution of 1-320. This serum (called Rochester No. 5) agglutinated 23 strains in dilutions of 1-320; 1 in a dilution of 1-640; 1 in a dilution of 1-80; 2 in 1-20; 2 strains failed to agglutinate and 2 cultures were lost before tests could be made. Strain No. 1 gave a positive test with this serum when a saline suspension was used for agglutinating but was negative with the peptone water culture. The Rochester serum agglutinated the 5 Albany strains of *B. dysenteriae* Sonne in dilutions of 1-160 and 1-320 and the strain of *B. ceylonensis* A as high as 1-320. This serum, while it agglutinated more strains than the Albany serum No. 1,621, proved no better than Albany serum No. 261.

Through the kindness of Dr. Koser, we obtained an immune serum prepared against a strain of dysentery bacillus isolated by Castellani and called by him *B. ceylonensis* A. Dr. Koser studied this strain and found it to be the same as *B. dysenteriae* Sonne. In running the tests with this serum, the first 10 strains were set up in duplicate using as antigens cultures in peptone water and saline suspensions. The results were the same with both antigens—all of the strains being agglutinated—so it was decided to set up the remaining 21 strains with the saline suspensions only. Out of the entire 31 strains this serum agglutinated 26 strains, failed to agglutinate 3, and 2 were lost. Two of the known strains of Sonne were agglutinated by the anti-ceylonensis serum, but the ceylonensis strain was not agglutinated by the Albany serum No. 1,621. There was insufficient quantity of serum No. 261 to use against the ceylonensis strain. It is obvious from these results that the serum sent by Dr. Koser is the best of the 4 serums studied.

A few agglutination tests were made, using the patients' serums, but as only 1 out of 7 was positive (strain No. 26 positive in 1-320; strains Nos. 1, 4, 5, 6, 7, 8 and 9 negative), no further attempt was made to obtain serum from the other cases in the hospital. Fraser, Kinlock and Smith⁷ reported positive results with patients' serums in from 7 to 20 days after the onset, and our failure to obtain similar results may have been due to the fact that the serums were collected from the patients too soon after the onset.

Culturally and serologically all of these strains fall into the same group and are identical with the 5 strains of *B. dysenteriae* Sonne isolated by the New York State Laboratory and with the strain of *B. ceylonensis* A isolated by Castellani. It would appear from the study of the serological reactions of these strains that it is difficult to produce an immune serum for *B. dysenteriae* Sonne which will agglutinate all strains. Until further work has been done, the use of more than one serum for the identification of an organism is recommended.

SUMMARY

The isolation of 31 strains of *B. dysenteriae* Sonne from an epidemic of dysentery in Rochester, New York, has been reported.

A cultural and serological study of the strains has been made and their reactions have been shown to be identical with strains of *B. dysenteriae* Sonne isolated by other workers.

Wassermann Reactions in College Students

HAROLD S. DIEHL, M. D.

Students' Health Service, University of Minnesota, Minneapolis, Minn.

ESTIMATES as to the incidence of syphilis among the general population of this country vary enormously. The syphilologist, the neurologist, and the criminologist encounter so many syphilitic persons that they are apt to believe that this disease is almost universal; while the general practitioner and the specialists in many other fields see, or at least recognize, so few cases of syphilis that they are likely to consider it a relatively rare disease.

The studies which have been made concerning the incidence of syphilis have been based upon 3 types of data: the number of cases actually under treatment in a given locality, the proportion of syphilitics among the patients of general hospitals or clinics, and the results of routine Wassermann tests of groups of supposedly healthy individuals.

Incidence of Clinical Syphilis—Stokes and Brehmer¹ reported in 1920 that of 1,563 consecutive patients studied at the Mayo Clinic, 3.1 per cent had syphilitic infections sufficiently obvious to be detected without the use of the routine Wassermann test. According to occupational groups, the incidence was as follows: male railroad employees, 11.7 per cent; laborers, 6.1 per cent; business men, 3.8 per cent; and farmers, 1.5 per cent.

In the opinion of these authors the percentage of syphilis recognized would have been higher had the Wassermann test been employed routinely. Parran, Smith and Collins² of the U. S. Public Health Service, in 1928 found that 0.67 per cent of the population of 9 cities and 5 counties in West Virginia, Kentucky, Illinois and Arkansas were under treatment for syphilis at the same time. King³ reports that 1.57 per cent of the enlisted personnel of the U. S. Coast Guard were under treatment for syphilis in 1929, and Stoner⁴ concludes from observations of general hospital patients over a 10-year period that the incidence of syphilis among white patients has been 5 per cent, but that there has been a large decline in the last 5 years.

The Wassermann Reaction—This test, while not infallible, is a

valuable aid in the diagnosis of syphilis; in fact, at certain stages of the disease it may be the only demonstrable evidence of infection. In late syphilis, particularly of the central nervous system, a negative blood Wassermann is not infrequent, but earlier in the disease the percentage of error is small. Stokes' reported that the blood Wassermann was negative in 53 per cent of patients with late syphilis; Duke⁶ found a negative reaction in 5 per cent of patients in whom chronic late syphilis could be demonstrated by other means; and Dodd⁷ considered 0.7 per cent of 200 pregnant women syphilitic in spite of negative Wassermanns.

Wassermann Surveys—Over a period of several years, a considerable number of surveys have been made upon groups of persons of various social, economic, and intellectual levels. The results of some of the more recent of these are summarized in Table I.

TABLE I
WASSERMANN SURVEY RESULTS

<i>Number Examined</i>	<i>Group</i>	<i>Place</i>	<i>Year</i>	<i>Sex and Color</i>	<i>Per Cent Pos. Was.</i>
12,115	Hospital patients	Toronto	1916-1925	Male—white	7.0
				Female—white	4.8 (7)
1,307	Hospital patients	Germany	1923	Both sexes white	7.3 (8)
—	Clinic patients	Mayo Clinic	1930	Both sexes white	4.3
				to	5.6 (9)
2,000	Pregnant Women	Edinburgh	1927	Female—white	6.7 (6)
4,000	Pregnant Women	Baltimore	1920	Female—negro	16.3
				Female—white	2.5 (10)
2,509	Rural	Mississippi	1929	Male—negro	23.6
				Female—negro	24.3 (11)
8,004	Prisoners	San Quentin, Cal.	1928	Male—white	7.2
				Male—negro	18.1
				Male—Mexicans	15.6
6,450	Soldiers	Camp Funston	1919	Male—Yellow race	24.3 (12)
		Fort Riley		Male—white	10.5 (13)
1,019	Recruits (less than one week in army)	U. S. A.	1915	Male—white	16.8 (14)
621	Student cadets	West Point	1915	Male—white	5.5 (14)
721	Cadet officers	Training Camps	1919	Male—white	0.6 (13)
3,203	Cadet officers	Training Camps	1919	Male—white	5.8 (15)

It will be seen that the incidence of positive tests among white males varies from 5.5 per cent to 16.8 per cent,* and among white females from 2.5 per cent to 6.7 per cent.

* With the exception of Levin's small group of cadet officers in which he found an incidence of only 0.6 per cent.

Wassermann Results Among Students—For several years, routine Wassermann tests have been performed as a part of the periodic health examination given to students in the upper classes at the University of Minnesota. These examinations are required annually of all students in the Colleges of Education, Dentistry, and Medicine, and are offered on an optional basis to seniors in other colleges. The tests are performed by the laboratory division of the State Board of Health. Cases giving a positive reaction are retested several times. Students whose blood gives doubtful positive reactions are studied clinically and the blood rechecked from time to time.

Over a 2-year period, 5,000 such routine tests have been performed upon students, and of this number 10 have shown consistently positive reactions. Five other blood specimens were reported as giving doubtful or weakly positive reactions, but since subsequent tests of these same students showed negative reactions, and clinical evidences of syphilis were lacking, these were not included in the group of positive reactors. This gives an incidence of positive reactors of 0.2 per cent for the group as a whole; the rate for boys being 0.17 per cent, and for girls 0.25 per cent.

Clinical Reports—Only one of these 10 students with consistently positive Wassermanns was aware of having had a syphilitic infection, although a woman, age 50, previously married, and a man, age 31, apparently suspected that they might have a venereal disease. Of the total cases, 5 were girls and 5 boys. Two of the girls had congenital infections. One was under treatment at the time of her examination and the other had received some intravenous medication after the death of her mother, but did not know for what purpose this was given and after a time discontinued the treatments; the third girl had had repeated headaches over a period of 4 years; the fourth had no symptoms except a secondary anemia; and the fifth was without suggestive symptoms of any kind. Of the 5 boys, 1 had a scar from a chancre and a history of a sore throat a short time previous to the examination; the second also had had what was probably a chancre but no treatment; the third stated that 6 or 7 years previous, after using a pipette in a drug store in which he was working he had a lesion in the mouth which was very slow in healing; while the fourth and fifth gave no history of either primary or secondary lesions. Stokes and Brehmer's report that in their series 24 per cent of the patients gave no history of primary lesions and 62.5 percent had observed no secondary symptoms.

Comment—Although the incidence of syphilis varies in different social, economic, occupational, and intellectual groups, Dublin and Clark,¹² after a thorough investigation of the reports up to 1921, con-

cluded that no less than 10 per cent of the population of our large cities have been infected with syphilis, and that "this percentage may well prove to be a safe estimate for the country at large." Since that time, the incidence of syphilis has declined somewhat in the army" and probably in the civilian population; although Detweiler' at the Toronto General Hospital, who noted a decline from 1916 to 1921, states that from 1921 to 1925 the figures have remained constant. However, even if one assumes that syphilis has been on the decline in recent years, the incidence of 0.2 per cent in this student group is but a small fraction of what one would have reason to expect to find in the general population.

In view of this low incidence, the question naturally arises as to how representative these university students are of the general population. The group, of course, is select in respect to age because although the age range of these 5,000 students was from 18 to 50 years, the mean was 23.7 years; the median, 23 years; and the mode, 22 years. In a similar but older group, the incidence rate probably would be somewhat higher; although the group of 6,450 recruits in which Levin" reported an incidence of positive Wassermanns of 10.5 per cent ranged from 21 to 31 years; and the Wassermann survey of negroes in Mississippi" showed the highest incidence of syphilis in the 30 to 39 year group and the next in the 20 to 29 year group.

The fact that these students had the intellectual capacity and ambition to reach the upper classes in the university adds a considerable element of selection in certain regards. Socially and economically, however, they come from practically every group in the community; in fact, 40 per cent of the boys and 13 per cent of the girls in the university are totally self-supporting; and all in all, they probably are quite representative of the more intelligent portion of our population.

Although the number of cases of syphilis which have been discovered in this group of students by the use of the routine Wassermann test is small, the diagnosis of this disease in an early stage is of inestimable value to those concerned. By the use of this test as a routine procedure, it has been possible to place them under treatment probably years before clinical symptoms would have been sufficiently definite for diagnosis.

CONCLUSION

1. Ten positive reactions considered as diagnostic of syphilis were obtained in 5,000 routine Wassermann tests performed upon students of the University of Minnesota. This represents a rate of 0.17 per cent for boys, 0.25 per cent for girls, and 0.2 per cent for the group as a whole.

2. Estimates as to the incidence of syphilis among the general population vary

from 2 per cent to 15 per cent, with 5 per cent to 10 per cent being most common.

3. Although the number of cases of syphilis discovered by routine Wassermann tests in this group is very small, the discovery of even these few cases before the development of late symptoms is extremely worth while and well justifies the inclusion of the Wassermann test as a routine procedure in every periodic health examination.

ARISTIDES AGRAMONTE, M.D.

THE death of Dr. Aristides Agramonte, at the age of 63, on August 17, adds to the already too long list of members whom we have been called upon to mourn recently, and removes the last member of the U. S. Army Commission which solved the problem of yellow fever transmission and its control.

Dr. Agramonte had recently been appointed Professor of Tropical Medicine at the Louisiana University Medical School, New Orleans, and was in that city for the purpose of organizing his department. His death was apparently unexpected, due to some heart affection.

It will be remembered that in October, 1930, he was made an Honorary Fellow of the American Public Health Association, and a sketch of his life and work, accompanied by a photograph, will be found in the JOURNAL for December, 1930, page 1333.

It is only necessary to add here that in the death of Dr. Agramonte science has lost a devoted servant. His knowledge of tropical diseases and his great experience in the practical handling of them made him peculiarly fitted for the professorship he had just accepted. Our growing international relationships, coupled with the development of rapid transit by steamship and airplane, have brought us every year more and more into contact with the diseases of other countries, and especially those in close contact with us on the south. The importance of tropical medicine has grown step by step with these contacts.

Personally, Dr. Agramonte was a charming man, characterized by unfailing courtesy to all with whom he came in contact. Many will remember with pleasure meeting him last year in Fort Worth and recall the scholarly address given by him at that time. We can ill afford to lose men of his character and accomplishments.

THE MONTREAL MEETING

THE 1931 Meeting in Montreal—the first in 37 years—will always remain a bright spot in the memory of all those who were fortunate enough to attend.

Montreal is a historic city. There are many places of great interest which some of our members have visited during the session. It is the seat of two large universities—one bearing the name of the city and the other McGill. McGill was the home of the late Sir William Osler's activities, and his library, which contains a remarkable collection of first editions of rare books, as well as much other material, is one of the interesting sights for all concerned with medicine and public health.

It is impossible to speak too highly of the perfection of the arrangements made for the Association. Every aspect of the entertainment as well as business was attended to in the best possible way. In a community in which French is largely spoken as well as English, the French and the English vied with each other in making our stay both pleasant and profitable. With no disparagement to other cities which we have visited in the past, it can be said without hesitation that never before has the Association been more cordially entertained with more abounding hospitality.

In spite of the distances which many members were obliged to travel, the attendance was good. It was, of course, somewhat influenced by the world-wide depression, but we have reason to feel that the selection of Montreal was wise.

The exhibits were of high quality and attracted much attention.

The sessions were well attended and special interest was shown in those which have a direct practical application to everyday problems, such as the immunization against diphtheria, the protection of milk supplies, and education.

The Executive Board sanctioned the proposition of the Committee on Membership and Fellowship for a drive for Life Members, from which we expect great things. Advantages—both to Members and to the Association—of Life Membership, have already been explained in the September issue of this JOURNAL (page 1027). It may not be out of place here to call attention to the fact that the payments can be made in installments.

What we hope will constitute an outstanding feature of the JOURNAL in the future is the arrangement which has been made with Charles Porter, M.D., Editor of *Public Health*, the official publication of the Society of Medical Officers of Health of Great Britain, for a monthly letter. *Public Health* will also publish an American letter monthly, to which the members of the Editorial Board of our Association will contribute.

One cloud has caused a shadow on our Meeting: The sudden death of our President-Elect, William C. Hassler, M.D., who was to have been inducted into office at the meeting.

We have been fortunate in obtaining the services of Louis I. Dublin, Ph.D., Statistician of the Metropolitan Life Insurance Company, for the ensuing year, under whose administration the Association is sure of wise counsel and direction.

We regret that there was no representation from our neighbors to the South (Mexico and Cuba), which played such a large part in our last Annual Meeting. We especially hoped to have Rafael Silva, M.D., our First Vice-President and Director of the Public Health Department of the Republic of Mexico, with us. On the other hand, we have been fortunate in having a delegation from England and one of the most interesting sessions was devoted to a discussion of the public health program of that country. We also noted with pleasure the presence of Peter H. Bryce, M.D., a former President and one of our honorary Fellows, and probably the oldest member of the Association.

This meeting is the first in which Kendall Emerson, M.D., Acting Executive Secretary, has officiated. We congratulate him on the success of his efforts.

John A. Ferrell, M.D., Dr.P.H., of the International Health Board of the Rockefeller Foundation was made President-Elect, and Thomas Parran, Jr., M.D., Health Commissioner of New York State, Treasurer.

CITY NOISE

THE modern public health movement is being extended from time to time to embrace additional phases of urban environment, which have public health aspects. City noise is a newcomer in this field, although the din of urban life has long been an important aspect of our municipalities. The rapid growth of automobile traffic, building operations, rapid transit and the like, however, has focused attention upon the necessity of controlling preventable noises to make urban life bearable.

This problem is very complex, both from an administrative and technical standpoint, embracing certain aspects of housing and zoning, building and construction activities, traffic regulations and nuisances

under the police and sanitary codes, as well as several distinct fields of science.

The consideration of the problem in New York and Chicago has led to the appointment of special noise abatement commissions with power to investigate the causes and effects of unnecessary noises and to develop procedures for their control. The Noise Abatement Commission of the Department of Health of the City of New York has prepared a comprehensive report upon its work entitled "City Noise." A study was made of the intensity of various noises throughout the city with special apparatus developed by the Bell Telephone Company and others. This permitted the preparation of a "spot map" of noises, and the quantitative analysis of the intensity from various sources.

The studies reveal that about 85 per cent of noise in downtown New York City is due to street cars, elevated trains, and automobile traffic. The control problem is thus largely restricted to the field of transportation. More efficient and quieter automobiles, trucks, and street cars are being developed, but there is great need for concerted effort in maintaining present equipment in proper operating condition.

Other municipal departments are more directly connected with the underlying problems of traffic and building regulations than health departments, and hence the subject must be viewed in its broad aspect, and not merely from the standpoint of public health. Specialists are of the opinion, however, that excessive noise causes permanent deafness upon prolonged exposure, such as in noisy industries. This is said to be due to the injury of the nerve endings of the auditory nerve when the protective mechanism of the ear is fatigued through prolonged excitation, thus preventing compensation for variation in the intensity of sound. Other specialists have stated that nervous strain results from prolonged exposure to noise, seriously depleting vitality.

As far as is known no correlation has been made between these physiological and psychological effects of noise and the data collected in the scientific study of the intensity of noise from various sources. It seems to be impossible, therefore, at present to select an intensity value, or "noise level" which would separate noises of public health significance to the general public and those of no such importance.

It is evident that further studies of this complex subject are needed, and that at present the regulation of noise should be through special commissions empowered to act through the provisions of municipal ordinances similar to anti-smoke ordinances. In this way, it is not necessary to prove the public health significance of any specific noise or group of noises in order that they may be controlled or eliminated. Hence it is possible in the present state of knowledge to institute noise control measures.

SIXTY-FIRST ANNUAL MEETING
 AMERICAN PUBLIC HEALTH ASSOCIATION
 Washington, D. C.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

THE NEED FOR CONTINUED STUDY IN PUBLIC HEALTH WORK

IN *Public Health Reports* of July 24, 1931, Volume 46, No. 30, there is a most interesting and enlightening article by W. S. Leathers, M.D., Dean of the School of Medicine, Vanderbilt University, Nashville, Tenn. Dr. Leathers points out how easy it is for a health worker to become a mere routine worker, and urges that serious consideration be given methods for continued study in public health work. He lists a number of methods for continued study, among which are:

1. Every health worker should read and be informed on current literature bearing upon the particular field in which he is engaged. Every health department, whether it be state or local, should provide three or more journals in which papers are published dealing with general or special phases of public health work.

Among the journals of value to public health officials, he lists the *Journal of the American Medical Association*, the *American Journal of Public Health*, the *Journal of Preventive Medicine*, the various publications of the U. S. Public Health Service, particularly the *Public Health Reports*, *Public Health Bulletins*, and the National Institute of Health *Bulletins*. Listed as bulletins dealing with special phases of clinical medicine and public health are such journals as the *American Journal of Hygiene*, the *American Journal of Tropical Medicine*, the *Bulletin of Hygiene*, *Journal of Industrial Hygiene*, *Public Health* (official organ of the Society of Medical Officers of Health of England), *American Review of Tuberculosis*, *Tubercle*, the *Jour-*

nal of Social Hygiene, the *American Journal of Diseases of Children*. The nursing personnel of the health department should be especially interested in the *Public Health Nurse*, and the *American Journal of Nursing*. The journal *Municipal Sanitation* will be found useful in dealing with problems of sanitation, such as water supply, sewage disposal, refuse disposal, and such matters.

2. Each department of health should provide a library with books on public health. Dr. Leathers points out that it would seem legitimate to use the contingent fund of the budget, within limitations, for purchasing certain books or subscriptions to journals. These may be added to by special donations on the part of individuals in the communities, or social agencies, such as federated and civic clubs, and the local medical society. There should be some method of encouraging systematic reading on the part of the health personnel. A program of reading could be adopted by the health officer as well as by the nurse, the engineer, inspector, or other workers, and discussions could be stimulated bearing on certain subjects in weekly or biweekly conferences.

3. The personnel of state and local health departments should regularly attend the annual conference of the state health department. The writer points out that following these meetings one frequently enters upon his task with vigor, and with new perspective, which indicates the unquestionable value of contacts of this kind.

4. It is most desirable that health

officers, engineers, nurses, inspectors, and others engaged in health work, attend meetings from time to time, which may be of regional or sectional importance. Particular attention is called to the annual meetings of the American Medical Association, where many papers are read in the section of preventive and industrial medicine and public health, which are of much interest and practical importance in scientific public health. The meetings of the American Public Health Association, which afford splendid contacts in the various sections, would provide opportunity for one to follow his interest in special phases of public health.

Special attention is called to the great importance of attending local medical society meetings, and the annual meetings of the state medical association.

5. Every health worker should become interested in a special problem, and should study it with a view to preparing a paper for some scientific meeting.

6. Dr. Leathers calls attention to the fact that the average health officer is apt to do too much spontaneous talking without preparation, and points out how much better it would be if one

were to select a topic, read somewhat on the subject, and prepare in a concrete way certain items which are relevant and which are productive of thought in the listeners.

7. One very important phase of study or reading is the history of preventive medicine and public health. Attention is called to *A Half Century of Public Health*, published by the American Public Health Association, and to *Pioneers of Public Health*, by Mrs. M. E. M. Walker, with a foreword by Sir Humphrey Rolleston, of Cambridge University.

8. Some plan should be worked out by each state so that the personnel of local health departments can avail themselves of continued study in post-graduate courses in certain universities. Short intensive courses of this kind can be made most helpful and constructive in building up one's professional background. These courses are referred to in England as "refresher courses."

The article contains a very useful appendix of books which health departments ought to have in their libraries, on all the various subjects connected with public health and its administration.

THE PHYSICIAN AS HEALTH WORKER

IN 1928 the Detroit Department of Health inaugurated a plan of participation by the general medical practitioner in the public health program of the city. A beginning was made by eliminating all free clinics for diphtheria protection, and since that date all work has been done by the medical practitioner in his own office.

The enterprise has been carried out jointly through the Public Health Committee of the County Medical Society and the staff of the Department of Health. During the past winter, at ten

conferences on communicable disease control, there was an average attendance of 235 physicians, and one-third of the membership of the Medical Society attended some one of the lectures. Preventive medical activities can be transferred gradually to the physician only through close working harmony with medical organization. At present there are 1,100 physicians in Detroit, or approximately 90 per cent of those who would be interested, who are coöperating in the diphtheria prevention program. The results indicate that 80 per

cent of the school children, and 70 per cent of the preschool group have received protection.

In addition to sponsoring post-graduate medical conferences, the Department of Health has inaugurated a program of popular health instruction and a system of home visitation and instruction of parents by public health nurses. When able to do so, the parents pay the physician \$1 for each dose of toxin-antitoxin or toxoid and also \$1 for the Schick test. When, in the physician's judgment, the parent is unable or unwilling to pay, the Department of Health reimburses the physician at the rate of \$.50 for each treatment and \$1 for the Schick test. The material used is furnished without charge to all physicians, and in turn the latter reports each treatment by postcard to the Department of Health. On June 1 it was found that 52 per cent of infants between 6 months and 1 year of age had received protection, while for the preschool group 70 per cent had been protected. The co-

operating physicians have been paid a sum in excess of \$100,000 or an average of \$142 per physician.

Not only has the coöperative campaign resulted in the protection of a large number of children, but the diphtheria death rate has been reduced to one-fourth of the level existing prior to the beginning of the plan. The attitude of the medical profession toward the work of the Department of Health has been changed with the elimination of the antagonistic feeling which too frequently exists toward the work of the public health nurse. A beginning has been made toward the establishment of a health center in the office of each physician, and the opportunity is offered to expand the program of health conservation with medical coöperation into other fields such as tuberculosis and cancer control, periodic general examination, and the health of mothers and infants. By L. O. Geib, M.D., and Henry F. Vaughan, Dr.P.H.—*J. A. M. A.*, 97: 366 (Aug. 8), 1931.

LABORATORY

JOHN F. NORTON, PH. D.

ISOLATION AND CULTIVATION OF THE WHOOPING COUGH BACILLUS, *HEMOPHILUS PERTUSSIS*

JOHN HAYS BAILEY, PH. D.

Laboratory of the Huesmann Memorial Research Foundation, James Whitcomb Riley Hospital for Children, Indiana University School of Medicine, Indianapolis, Ind.

THE isolation of most organisms of the respiratory tract is dependent upon direct swabbing of the tract or recovery of the organisms from secretions of these organs. These methods are of great importance and yield very satisfactory results in diseases where the or-

ganism sought is located in regions easily reached by the swab, or where the secretions containing the organism can be readily collected.

In the case of whooping cough, however, if Mallory¹ be correct in his views on the pathological lesion in pertussis,

the organism is located below the larynx and, therefore, inaccessible to the ordinary swab. The use of sputum for isolation of *Hemophilus pertussis* is not entirely satisfactory, as most small children swallow any sputum expelled in a paroxysm. Also, since the organism is found deep in the trachea and bronchi, the easily expelled sputum—that from the upper portion of the respiratory tract—would not be expected to contain the organism, necessitating obtaining the thick, ropy mucus that is finally expelled before any hope of finding the organism may be entertained.

These difficulties can in a large measure be overcome by the use of the cough plate method of isolation of the *H. pertussis* devised by Chievitz and Meyer in 1916.² Plates containing Bordet-Gengou medium are held 3 to 4 inches from the mouth of the coughing patient. Merely asking the patient to cough and exposing the plate during such an effort will not yield good results. The exposure must be made during a genuine paroxysm. After exposure the plates are incubated for 3 days. At the end of that time they are examined for colonies of *H. pertussis*. These are found to be small, grayish-white, somewhat glistening, translucent, raised colonies, usually surrounded by a dark zone of hemolysis. This latter condition is by no means constant. The colonies may be readily picked off the surface of the medium.

Suspicious colonies are then examined by a Gram stain. It is very dangerous to make a diagnosis of a positive cough plate by cultural characteristics alone. Not infrequently pure cultures of *H. pertussis* are obtained by this method, although as a rule the plates contain large numbers of saprophytic bacteria. Indeed it is the saprophytes of the respiratory tract that offer the most serious handicap to the isolation of *H. pertussis* by overgrowing the entire plate in the time necessary for the growth of

the latter, and crowding out or obscuring the pertussis colonies. This handicap may to a certain extent be overcome by proper exposure of the plate.

By allowing the paroxysm to continue to a deep bronchial expulsive effort and then exposing the plate, the saprophytes are largely washed out of the mouth and upper trachea, and the organisms contained in the air or droplets of the final efforts may be deposited upon the plate. It is just here that most failures of the cough plate method occur. If the plate be exposed before the saprophytes are washed out the result is likely to be an overgrown plate. With a little experience no difficulty is encountered in obtaining positive cough plates during the favorable period of the disease, that is during the first 2 weeks. In practice, plates should be exposed in duplicate, affording a better chance of obtaining the organism. If one of the plates is positive the other need not be examined.

The medium used by Chievitz and Meyer was the original Bordet-Gengou medium—a glycerinated extract of potato with horse blood in place of the rabbit or human as recommended in the original.

We have found a modification, developed in Madsen's laboratory, of the original Bordet-Gengou medium to give the most satisfactory results. Pared potatoes are cut into thin slices. To one kg. of potato are added 2,000 c.c. of water and 80 c.c. of C.P. neutral glycerine. This is boiled over a free flame until the potato falls to pieces, the water lost by evaporation being replaced. The material is then rubbed through a sieve and strained through a towel. The expressed juice is then adjusted to a pH of 7. To 1 part of neutralized juice (it is rather thick) is added 3 parts of 0.6 per cent sodium chloride solution. The material is then distributed in 200 c.c. lots into 500 c.c. flasks. To each flask is added 8 to 10

gm. of agar. The flasks are then plugged and set in the ice chest over night. If powdered agar is used it is not necessary to store over night. The flasks are then autoclaved at 15 lb. pressure for 30 minutes. When plates are to be poured the agar is melted and then cooled to about 40° C. Two hundred c.c. of sterile defibrinated horse blood, warmed to about 40°, is added and thoroughly mixed. To the resulting mixture 6 c.c. of sterile N/2 lactic acid is added and mixed. Plates are then poured and one plate is incubated for 2 to 3 days to test the sterility. This plate is not used again.

Plates of this medium may be stored in the ice chest for 2 weeks. It is important that the agar be not too hot at the time the blood is added, as *H. pertussis* grows only on unaltered hemoglobin. Indeed this fact has been used as a method for identifying *H. pertussis* and differentiating it from *B. influenza*; the latter grows on chocolate agar, the former will not until after several generations on artificial medium.

When cough plates are to be used in a hospital or institution the usual Petri dish is used, but where the plates must be sent some distance to the laboratory these are, of course, out of the question. An aluminum dish, 90 x 10 mm. in height and resembling the usual Petri dish, is very satisfactory for use as a cough plate. It is easily handled, is about the weight of the glass dish, and cannot be broken. Steam will corrode the dish, but, after soaking in 3 per cent phenol, rinsing and drying, it may be sterilized in the hot air oven at 200° to 250° C. The usual culture box as used in diphtheria diagnosis or the tin ointment boxes used for the same purpose are not as satisfactory as the larger dish, though they may be used.

It is true that these small boxes save the culture medium, and do not allow the medium to dry out as do the other dishes, but the surface of the medium

exposed to the expelled air at the time of exposure of the plate is so limited that the chances of getting a positive plate are much decreased. The small surface also allows a more ready overgrowing of the plate by saprophytes. The tight fitting covers, while keeping the medium in good condition, make it difficult to open the box to expose it. Of course, the metal dish has a big disadvantage in that it is impossible to see the medium without opening it, thus risking air-borne contaminants. With the glass Petri dish, overgrowing may be prevented to a large extent by cutting out, with a sterile instrument, colonies that are spreading so rapidly that there is danger of overgrowing.

While blood is absolutely essential in the culture medium for the isolation of *H. pertussis*, it is not necessary after a few generations on Bordet-Gengou medium. An excellent medium for growing *H. pertussis* is one containing equal parts of Bordet-Gengou stock, nutrient agar and horse blood. Two hundred c.c. of nutrient agar and 200 c.c. of Bordet-Gengou stock are pooled and sterilized. When cooled to about 40° C. 200 c.c. of sterile defibrinated horse blood are added. The pH of the nutrient agar is about 7.8. *H. pertussis* can be grown on this medium directly from the cough plates; in addition it is an excellent one for growing the organism for vaccine.

After several generations on an artificial medium, good growths may be obtained by using any of the following agars: brain, chocolate, hormone, ascites, or veal infusion. The first and last named mediums are to be recommended for the ease in preparation and sterilizing.

The brain agar, suggested by Pelouze and Viteri³ for the culture of gonococcus, is to be highly recommended. Their directions are as follows: 500 gm. of calf brain are forced through a wide meshed wire gauze into 500 c.c. of dis-

tilled water. This is allowed to infuse 24 hours in the ice chest. It is then slowly brought to 75° C., kept there for 30 minutes and then put through several cotton filters of varying thickness. The filtrate will always be turbid. To this is added sufficient acid sodium phosphate and peptone to yield a 0.5 per cent and 1 per cent solution respectively. This is the stock and is autoclaved for 20 minutes at 15 lb. pressure. To complete the medium 1 part of the stock brain broth is added to 3 parts of standard 1 per cent peptone veal broth agar. The agar should be 3 per cent* and the pH adjusted to 7.8. The medium is then tubed and autoclaved. The original method did not allow heating the brain infusion, but this practice does not interfere with the growth of *H. pertussis* and is a big aid in the filtering of the infusion.

The growth of *H. pertussis* on veal infusion agar is less luxurious than on the other medium but it may be enhanced by the addition of glycerine. This medium is the one in routine use

* The original method calls for 2.5 per cent agar, which when diluted gives too soft a medium.

for stock cultures of *H. pertussis* in this laboratory. It is essential that the broth be as free from fat as possible, so the meat is purchased in chunks, never ground, and the fat removed in the laboratory. The infusion is made to contain 2 per cent peptone, 5 per cent glycerine, 0.5 per cent sodium chloride and 2.5 per cent agar. The pH is adjusted to 8.0 and the medium sterilized, filtered through cotton, tubed and re-sterilized at 15 lb. for 30 minutes. The final pH is 7.6.

Certain veal known to the packers and butchers as "red" has, in the experience of this laboratory, been less satisfactory for pertussis culture medium than the so-called "white" veal. Calves that have been shipped some distance and then slaughtered, particularly those that have had a milk deficient diet, give "red" veal. Some veal may be of such a deep color it resembles beef; such veal is all but useless for pertussis culture medium.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Vital Statistics for Georgia, 1930—For the calendar year, 1930, there were registered in the State of Georgia 60,318 live births, corresponding to a birth rate of 20.7 per 1,000 population. This represents an increase of 1,804 births over the number (58,514) of births registered in 1929. The total number of deaths reported for 1930 was 35,188, corresponding to a death rate of 12.1 per 1,000 population. This rate represents a slight decrease (0.8 per cent) over the rate (12.2) recorded in 1929. The annual average number of deaths reported in the last 10 years in Georgia was 32,981, representing an annual average rate of 11.4. Death rates for the past 10 years show an annual average increase of 0.1. Stillbirths, numbering 3,796 or a ratio of 6.3 per 100 live births, showed an increase of 255 over the number registered in 1929. The number of deaths of infants under 1 year of age registered in 1930 was 4,713, corresponding to an infant mortality rate of 78.1 per 1,000 live births, as compared with 4,469, or a rate of 76.3 in 1929, the 1930 rates showing an increase of 2.4 per cent over the 1929 rate.

Among the communicable diseases, smallpox with no deaths in 1930, malaria with a death rate of 15.2 in 1930 as compared with 23.3 in 1929, diphtheria with a 1930 rate of 4.6 as against 6.3 in 1929, and influenza with a rate of 33.1 in 1930 as compared with 87.5 in 1929, showed the most striking reductions in death rate. On the other hand, typhoid fever and measles showed increases from 11.7 and 1.1 respectively in 1929 to 16.9 and 4.4 respectively in 1930.

Heart diseases with a rate of 140.7 in 1930 and nephritis (129.9) were the leading causes of death in 1930, heart disease having shown a marked increase from the 1929 rate of 126.9, and nephritis a marked decrease from the 1929 rate of 137.7. Cancer (53.3), diabetes (12.1), cerebral hemorrhage, softening (87.0), pneumonia—all forms (88.5), diarrhea and enteritis—2 years (24.7), and other puerperal causes (17.1) were most important among the diseases showing increases in 1930 over 1929, while pellagra (24.5) showed a considerable decrease. The tuberculosis decline from 75.3 in 1929 to 74.6 in 1930 is noteworthy.—*Official Bulletin on Biennial Report of the State Board of Health of Georgia, 1929-1930*, pp. 65-75.

Some Vital Statistics for Pennsylvania, 1928-1930—According to the biennial report of the Department of Health, the birth rate of Pennsylvania, with its population of approximately 10,000,000 people, has been falling for the last 25 years, with a temporary increase in the year 1920 and in 1921 following the return of the men who were in the Army. In 1910 there were 7,600,000 people in Pennsylvania. With that population there were 203,510 babies born during the year, corresponding to a birth rate of 26.5. In 1929 there were 189,524 live births with a rate of 19.6 per 1,000 population. There has been a corresponding decrease in marriages, which have fallen from a rate of 16.2 per 1,000 population to 14.2 in the 20 years indicated.

In 1929 there were 117,365 deaths, bringing the death rate to a new low

level of 11.9 for the State of Pennsylvania. It is interesting to note that despite the great increase in population from 1910 to 1929, there were actually more deaths (119,815) from all causes in 1910 than in 1929.

The infant mortality rate in Pennsylvania has been reduced from 167 per 1,000 living births in 1906 to 71 in 1929 and the indications point to a further reduction when the records of 1930 are complete.

Among the contagious diseases, typhoid fever has become practically a negligible factor. In 1906 there were 3,917 deaths from typhoid, in 1929 only 201 individuals died from this disease, giving a mortality rate of 2.0 per 100,000 and a morbidity rate of 12.7, the lowest in the history of the state. The 6 months of 1930 show a further reduction with a mortality rate of 1.1 and a morbidity rate of 6.3 for the half year.

Only 1 death from smallpox has been reported in Pennsylvania since August, 1925. In 24 years of registration in Pennsylvania there have been 9 years in which not a single death from smallpox has been reported. The year 1929 established a new record in diphtheria both in the death rate and in the case rate, the former dropping to 6.9 per 100,000 population and the latter to 75.0. This can be compared with the year 1921 when there were 20,910 cases and 1,983 deaths, while in 1929 there were only 685 deaths and 242 in the first 6 months of 1930. In 1929 there were 7,422 cases of diphtheria and in the first 6 months of 1930 there were 3,462.

The maternal death rate for 1928 was 5.8 per 1,000 births; for 1929 it was 6.1. This is an apparent rather than an actual increase due to the fact that it is rated on the number of births and this number has been decreasing, but at the same time an analysis of the record shows that there has been no definite im-

provement in lessening the perils of women at childbirth in recent years.

Deaths from all accidental causes in Pennsylvania continue to increase, but if those caused by automobiles are removed, the industrial deaths show a very definite decrease.—Commonwealth of Pennsylvania. *Biennial Report of the Department of Health, 1928-1930*, pp. 6-9.

Population of the United States by Sex, Color, and Nativity, 1930—As shown by the Fifteenth Census, the total population of the United States on April 1, 1930 (122,775,046), comprised 62,137,080 males and 60,637,966 females, or 102.5 males per 100 females. In 1920 there were 53,900,431 males and 51,810,189 females, or 104.0 males per 100 females. The number of males in 1930 exceeded the number of females by 1,499,114, and in 1920 by 2,090,242. These figures would indicate that the female population had increased somewhat faster than the male population.

The native white population of native parentage comprised 48,010,145 males and 47,487,655 females. There were thus 101.1 males per 100 females, which may be compared with 101.7 in the same class in 1920. Among the native whites of foreign or mixed parentage there were 12,550,144 males and 12,811,042 females, or 98.0 males per 100 females, as compared with 98.6 in 1920. The foreign born whites comprised 7,153,709 males and 6,212,698 females, or 115.1 males per 100 females, as compared with 121.7 in 1920. The 1920 sex ratios for native whites of foreign or mixed parentage and for foreign born whites are made slightly higher by the inclusion in that year of persons who would have been classified in 1930 as Mexican. The effect of this inclusion is so slight, however, that it has not been thought worth while to present adjusted figures for comparison.

The Negro population comprised

5,855,669 males and 6,035,474 females, or 97.0 males per 100 females, as compared with 99.2 in 1920. The sex ratio (males per 100 females) for the Mexican population in 1930 was 114.3; for the Indian population, 105.1; for the Chinese, 394.7; and for Japanese, 143.3.

There are considerable differences in the sex classification of the population as among the three general sections of the country—the North, the South, and the West.

The number of males per 100 females in the North in 1930 was 102.2, or practically the same as for the country as a whole. In the South the number of females was relatively higher, the sex ratio being 100.9. In the West the number of males was relatively much larger, the sex ratio being 109.5. For the native white population of native parentage, the sex ratio in the North was 101.6; in the South, 102.2; and in the West, 106.0. For the foreign born whites the differences are more pronounced, the ratio for this class in the North being 112.3; in the South, 130.2; and in the West, 133.9.

Among the Negroes in the North there were 101.0 males per 100 females; in the South, 95.9; and in the West, 104.1. The somewhat higher ratios shown for the North and the West indicate that in the migration of Negroes from the South, males have been somewhat more numerous than females, though the excess is not very great.

While the number of Mexicans is relatively small as compared with the other races, the differences in the sex ratios in the different areas are interesting. In the North there were 65,451 males of this race and 39,535 females, or 165.6 males per 100 females. In the South (the Mexicans in this section being mainly in Texas) the sex ratio was 106.1, and in the West, 116.9.—Department of Commerce, Bureau of the Census, Population U. S.—3, Aug. 18, 1931.

Statistical Notes on the Census for England and Wales, 1931—The total population enumerated in England and Wales as at midnight on Sunday, April 26th, 1931, according to preliminary summaries furnished by local Census Officers, was 39,947,931 persons, 19,138,844 being males and 20,809,087 females.

The present total is the largest hitherto recorded in England and Wales; and the areal density it represents, viz., 685 persons per square mile, is, with a possible exception in the case of Belgium, far higher than that of any country of which the Census Office has record—much more than double that of a large majority of other countries.

The 1931 total population exceeds that returned at the previous enumeration of the 19th of June, 1921, by 2,061,232, corresponding to an intercensal rate of increase of 5.44 per cent, or, if allowance is made for the 54 days by which the intercensal period falls short of the full 10 years, a decennial rate of increase of 5.52 per cent. The numerical increase is less than that of any decennium since 1861 (when the population was half its present dimensions) with the sole exception of the war decade 1911–1921; while the percentage increase, with the same exception, is only half or less than half of any previously recorded. But for the exceptional loss of men during the war the present decennial rate of increase would have been the lowest recorded for England and Wales since Census taking was introduced in 1801.

In spite of the fact that marriage rates have been well maintained, particularly at the younger ages at which the bulk of births occur, and of the further fact that the exceptional post-war spurt in the birth rate itself had only just passed its maximum at the beginning of the decennium, the total births registered in the 1921–1931 intercensal period are more than a million and a

quarter (16.3 per cent) fewer than in the preceding period—a period which covered the war years when the birth rate sank to levels never before recorded in the country. They are between 2 and 2½ millions (25.4 per cent) fewer than those of the last completely normal decennium 1901–1911.

The almost unbroken fall in the birth rate during the past 10 years has reduced it to a level of 16.3 per 1,000 population, a figure which is only half, or less than half that experienced prior to 1890 and only about two-thirds of that recorded in pre-war years. With the exception of Sweden, England and Wales now has a lower birth rate than any other country; and the present rate is definitely insufficient to maintain a stationary population in the future. It has been suggested that a current birth rate of about 19½ per 1,000 population would be necessary if a future decline in population were to be avoided. The actual level at the moment is 16 per cent below this standard.

As a partial off-set against the decline in births, the deaths registered on the intercensal period were more than ½ million fewer than those of either of the two preceding decennia. This numerical reduction of more than 10 per cent, if allowance is made for the increasing age and numbers of the population exposed to risk, represent a reduction in true mortality of more like 20 per cent compared with the decennium 1911–1921 (exclusive of deaths on active service) or 30 per cent compared with the last pre-war decennium, 1901–1911.

The movement of population other than that accounted for by the difference between births and deaths has been outward on balance and has resulted in a loss of population amounting to 177,000 persons.

In each of the regions of England and Wales except South Wales (W. I.) the population of 1931 is greater than it

was in 1921. The variations range from an increase of 10.5 per cent in the South Eastern section to the decrease in South Wales of 3.6 per cent, both these extremes standing prominently apart from the movements in the intermediate areas, of which only one (M. 2) is just above, while eight are below, the national average.

The most striking contrast in the current increases stands in relation to those of 10 years ago. The areas associated with mining and heavy manufacturing industries which produced the largest population growths in 1911–1921 now take up positions at or near the bottom of the list, notwithstanding their relatively high birth rates, whereas the South Eastern region now outstandingly at the top formerly registered an increase below the general average. Considerable retardation of growth is recorded in the northern textile regions; but on the other hand the increases in the rural counties of the East and South West—especially the latter—show definite acceleration, though they are still under average.

Of the urban and rural administrative areas into which the country is divided, the population of the 1,120 urban areas (including County and Municipal Boroughs and counting the Administrative County of London as one district) amounted in all at the date of the census to 31,948,166 persons while the population of the 638 Rural Districts amounted to 7,999,765, so that the proportions now living under urban and rural conditions may broadly be regarded as 80 and 20 per cent respectively.

The subdivision of the urban population into a large number of separate units discloses, as might have been expected, a wide range of increase and decrease variations. During the period 1921–1931, 14 towns have more than doubled their populations; in these the increases rise to the extraordinary per-

centages of 796 in Kingsbury (Middlesex), 879 in Dagenham (Essex) and 1,019 in Welwyn Garden City (Herts). On the other hand the number and magnitude of the decreases now recorded are much greater than they were 10 years ago. In 468 towns the populations have fallen, the loss exceeding 20 per cent in twenty areas, as compared with 370 and 6 respectively in the preceding period. But here, again, caution must be used in comparing census populations, for, as indicated above, it is necessary to bear in mind that many seaside and holiday resorts were inflated by temporary visitors in 1921 owing to the postponement of the census of that year to the middle of June, with the result that the progress of such areas will be underrated by their latest figures to the extent to which it was overstated in 1921.

More than one-half of the total population of the country is aggregated in comparatively dense units containing more than 50,000 each, and one-half of this population or one-quarter of the whole is to be found in the 13 largest towns (counting London as one) with

populations exceeding a quarter of a million.

The preponderance of females over males, which rose from an excess of 1,179,276 in 1911 to 1,736,221 in 1921 as a direct result of the loss of men during the war, has fallen in the last 10 years to 1,670,243. The exceptional war element will, of course, be visible in the population figures for many decades to come; it will, however, occur at increasingly older ages and at the present time is located mainly between the ages of 30 and 55 instead of between 20 and 45 as at the census of 1921. The excess in all cases is obtained from the number of the sexes enumerated within the country, and omits from account members of the armed forces and of the mercantile marine absent from the country on census night. The present excess represents a ratio of 1,087 females to 1,000 males. It is higher than any corresponding ratio prior to 1921 and compares with a pre-war ratio of 1,068.—Census of England and Wales, 1931, *Preliminary Report*, pp. x-xxi, Aug.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

EFFECTS OF MANGANESE ON FILTER OPERATION

LEWIS V. CARPENTER

Professor of Sanitary Engineering, West Virginia University, Morgantown, W. Va

THE appearance of manganese in the surface water supplies of northern West Virginia has been closely allied with the development of bituminous coal mining and the subsequent acid drainage entering the streams. It was first noticed in the color of the sand grains in the filter beds. The sand appears black when wet but its color changes to a dark brown when dry. After the filter has colored, the tubes of the chlorinators darken, and deposits of manganese collect on all parts exposed to water and chlorine.

Three filter plants all of which are located on the Monongahela River watershed in West Virginia were selected as a basis for the facts in this paper. Plant No. 1 of Weston takes its water supply from behind a low dam across the West Fork River. This supply is badly polluted with sewage.

Plant No. 2 at Clarksburg is about 25 miles down stream from Plant No. 1 and takes water from the same stream. Several small towns empty untreated sewage into the river. Also a number of bituminous coal mines discharge acid drainage into the stream above the water intake.

Plant No. 3 at Morgantown on the Monongahela River is about 40 miles down stream from Plant No. 2. It receives the untreated sewage from 100,000 people together with a large amount of acid mine drainage so that during times of low flow the water is practically sterile.

EXAMINATION OF FILTER SANDS

During the past summer samples of sand from each of the three filter plants were collected and tested. Table I gives the results. Unfortunately the mechanical analyses of the sands at the time they were placed in the filters were not available, but certainly the effective sizes were much lower when the filters were first placed in operation.

TABLE I

Plant No.	MECHANICAL ANALYSIS OF FILTER SANDS		CHEMICAL ANALYSIS	
	Effective Size mm.	Uniformity Coefficient	Manganese %	Calcium %
1	0.51	1.53	0.50	0.48
2	0.60	1.38	1.10	0.12
3	0.63	1.65	0.51	0.52

The manganese and the calcium contents were based upon the total weight of the sample and it is easy to account for the high effective size.

All three plants use lime and alum for coagulation and are operated by competent men. The effective size of sand increases with each plant while the manganese content at Plant No. 2 is the highest. The water used by Plant No. 3 has been diluted by several streams after leaving Plant No. 2.

EFFECTS ON OPERATION

The manganese content of the raw water at Plant No. 2 rose from 1.0 p.p.m. in June to 2.0 in August and continued at that figure until December when it jumped to 3.0 and remained there until flood stage on January 6.

Unfortunately these three plants do not make the test for manganese as a routine test and it is not possible to say what part of the time manganese is present in the raw water. The writer has tested the raw water at each source a number of times and always found at least a trace present. The Monongahela River has a manganese content of from 5 to 12 p.p.m. during times of low flow.

A large amount of manganese is deposited on the filter sand but some goes through as shown by the black deposit on the chlorine machine.

The removal of manganese is effected by the elimination of all free carbon dioxide and carrying the applied water with a pH value of about 8.3. Possibly, now that the filters have become encrusted with manganese, the water, in passing through, takes up the manganese, especially when free CO_2 is present in the water.

As all of these plants use alum for coagulation at least a part of the manganese in the finished water is a result of this re-solution. Mr. Boynton, at Clarksburg, writes:

We are dosing for turbidity once more and so cannot dose with lime as heavily as in times of drought, but I am adding lime before filtration, to phenolphthalein alkalinity of 5-8 p.p.m., to remove small amounts of manganese and to prevent re-solution of same from filters.

Morgantown did not have trouble with manganese after they increased the lime dosage so that the water on top of the filter had a few parts per million of phenol alkalinity. At Weston very little trouble has been experienced with manganese in the effluent.

Chlorination of the raw water in doses as great as 5 p.p.m. does not oxidize the manganese. Laboratory as well as plant tests indicate that lime in sufficient quantities to remove the CO_2 and bring the pH value above 8 will cause the manganese to be precipitated. The filter operator must use this heavy dosage of lime or it will be carried over onto

the filters. This deposit will, as stated before, encrust the sand grains and with accompanying growths of slime and bacteria, shorten filter runs and lower the rate of filtration.

EFFECTS OF FILTRATION

At the Weston plant the filters are badly caked. The filters are washed by applying air and then water at a high velocity. The capacity of the sewer is not large enough to take care of the quantity of wash water and the water at times during washing is a foot over the wash water gutters. The filters are not equipped with loss of head gages and during the summer they were washed shortly before the filters were placed in operation. There is adequate filter area, so the effects of poor washing are minimized by the slow rate of filtration. During idle periods gas bubbles come up through the filters. The bacteriological results on the effluent are usually good, but during the summer months the effluent had a disagreeable decayed vegetable taste. The sand has been recently renewed and more tests will be made later.

At Clarksburg the filters are in excellent condition and the only apparent bad effect of the manganese has been its occasional presence in the filtered water. Mr. Boynton writes:

Up to the present time no decrease in efficiency of the sand beds has been manifest, the water passing through clear and sparkling and of low bacterial content. *B. coli* is not found with increasing frequency in the effluent, but in varying numbers, according to the load, as was the case when the sand was clean.

At all times the bacteriological quality of the Clarksburg water is excellent.

At Morgantown the total count in the raw water during the times of low flow is so low that it is not possible to detect any ill effects of the manganese deposits on the sand grains. The river water is usually sterile and its turbidity 0. The pH frequently is as low as 3.0.

CONCLUSIONS

1. The increase in size of sand grains due to deposits of manganese probably decreases the efficiency of filtration, but the load on the filter plants studied is not sufficient to make an unsafe effluent.

2. Elimination of free CO_2 and the addition of lime to bring the pH up to about 8.3 will cause the manganese to be deposited in the basins.

3. After the sand grains have become coated with manganese, water containing free CO_2 will dissolve some of this deposit and cause manganese to appear in the effluent.

4. More data are needed on the safe load on a rapid sand filter when the effective size has been increased by manganese deposits.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Antirachitic Potency of the Milk of Cows Fed Irradiated Yeast or Ergosterol—The experiment here reported was carried out on cows in a large model dairy herd. They were divided into 5 groups, 2 of which received fodder supplemented with irradiated ergosterol, 2 fodder supplemented with irradiated yeast, and 1 served as a control. The cows were confined to their stalls at all times so that sunlight played no rôle in the results.

One group received the equivalent of 100,000 rat units of irradiated ergosterol in the form of viosterol—a solution of this sterol in corn oil. Another group received 200,000 rat units of viosterol. Two other groups were given supplements of irradiated dried brewer's yeast, one the equivalent of 30,000 rat units a day and the other the equivalent of 60,000 rat units. The fifth group or control received only the basal diet.

Infants, 4 groups of about 25 each, were given the milk from these cows, 2 of the groups receiving the "irradiated ergosterol milk" and 2 the "yeast milk."

Before the tests were begun a care-

ful examination was carried out with especial attention to the presence of rickets. The test was carried out for 3 months, and although the main object was the prevention of rickets, the investigation also afforded an opportunity for a curative test as at the beginning 13 infants were found to have roentgenologic rickets and 36 some evidence of clinical rickets.

Of the 4 test milks given, all except the weaker "yeast milk" were found to prevent as well as to cure rickets. In cases in which rickets was already present the milk brought about calcification within a month. From the point of view of the number of antirachitic rat units fed to the cow, the irradiated yeast induced a more potent milk than the viosterol. The outstanding advantage of this method of antirachitic therapy is that it functions automatically.—A. F. Hess, J. M. Lewis, F. L. MacLeod and B. H. Thomas, *J. A. M. A.*, 97: 370 (Aug. 8), 1931.

Salmon Poisoning—This disease of the *Canidae* occurs in western Oregon, northwestern California, and southwestern Washington. Apparently this disease has been indigenous to this region

before it was settled by whites. One of the authors had previously reported that this disease was associated with infestation with an intestinal fluke, an encysted form of which occurred in fish.

This paper reports an extensive investigation of the cause and nature of salmon poisoning. Attention is given to the description of the fluke and its life cycle based on field studies which revealed the identity of the snail host. The distribution of this snail was found to be practically identical with the distribution of salmon poisoning. Encysted flukes were found present in salmon and trout only in fresh water where the snail host was always present.

The authors succeeded in experimentally infesting fish with the parasite by contact with the snail host under controlled conditions. Field studies indicate that fish may become infested during any season of the year. All genera and species of the family *Salmonidae* occurring in western Oregon streams have proved to be hosts of this fluke.

Studies of the pathogenicity of the parasite show that in dogs, foxes, and coyotes, a typical syndrome follows the consumption of infested salmon and trout.

Numerous experiments were carried on to study the nature of the disease. The symptoms, pathology and immunology are given in detail and are suggestive of an infection. While it is apparent that ingestion of parasitized fish and subsequent infestation is a predisposing cause of the disease, the specific cause was not demonstrated.

Experiments were also conducted which showed that injections into experimental animals of large numbers of parasites heated at 60° C. for 1 hour, at 100° C. 4 minutes, and 100° C. 3 minutes, did not produce any symptoms of salmon poisoning. The same experiments in which parasites held at low temperatures were used also failed to

produce symptoms in experimental animals.

In summarizing their work the authors concluded:

1. Salmon poisoning is a disease of *Canidae* associated with the trigenetic intestinal fluke *Nanophyetus salmincola* Chapin.

2. The flukes reach maturity in from 5 to 7 days in the mammalian host.

3. The snail host is *Goniobasis plicifera* var. *silicula* (Gould). The fish hosts include salmon and trout from western Oregon. The mammalian hosts include dogs, foxes, coyotes, racoons, bobcats and minks.

4. Of the mammalian hosts only the *Canidae* develop the disease.

5. The specific cause of salmon poisoning is unknown.

6. The disease has a definite incubation period, followed by typical acute symptoms, and high mortality. Significant pathological lesions are limited to the digestive tube.

7. No satisfactory treatment has been found.

8. Recovery is followed by a definite immunity.

9. Attempts at producing immunity have been unsuccessful.

10. Interperitoneal injections of mature flukes resulted in producing symptoms similar to those produced by eating parasitized fish.

Studies in Nutritional Anemia. Quantitative Variations in Iron, Copper, and Manganese Supplements—An extensive series of experiments was undertaken by the authors in an attempt to explain the discrepancies in results reported previously by several investigators. Secondary anemia was produced in young rats by feeding fresh milk from the time of weaning. Aluminum and block tin were the only metals which came in contact with the milk before feeding. Hemoglobin determinations were made weekly on each animal until a normal level was reached, after which bi-weekly determinations were made. Tables and charts are given summarizing the results obtained.

There was found to be slow but definite hemoglobin response to pure iron salts. The response is directly proportional to the amount of iron fed within the limits tested in the experiment. The optimum daily dose of copper for a rat appeared to be between 0.1 and 1.0 mg. daily.

Manganese fed in 0.1, 0.05, 0.025, and 0.01 mg. doses daily has a negligible supplementary action to iron in hemoglobin synthesis, but may have a slight stimulating effect on growth and food intake. Higher doses of manganese are being investigated further.

The optimum daily iron requirement for a rat is around 0.25 mg. if sufficient copper supplement (0.1 mg. daily) is provided.

When recovery from a nutritional anemia is the experimental procedure a uniformly low initial hemoglobin in experimental animals is essential for consistent results.—Helen S. Mitchell and Lila Miller, *J. Biol. Chem.*, 92: 421 (July), 1931.

The Basal-Metabolic Rates of Vegetarians—Previous work (Benedict and Roth, *J. Biol. Chem.*, 20: 231, 1913) has indicated that there is little, if any, difference between the basal-metabolic rates of vegetarians and non-vegetarians.

In the work here reported, the group

chosen for study consisted of nurses, between the ages of 18 and 25, in training at a vegetarian sanitarium and living under uniform conditions of diet, work and general environment. No subjects who were more than 10 per cent over or under weight, or who showed symptoms of poor health or other abnormality, were included in the group. The Du Bois standards of normality were used as the basis of comparison.

Five girls were classed as life-long vegetarians, having never eaten meat of any kind in their lives. Their average basal-metabolic rate was 14 per cent below the normal of Du Bois. Ten girls were classed as long-time vegetarians, having been non-meat-eaters for 5 years or more. Their average basal-metabolic rate was 12 per cent below normal. To check this, the basal-metabolic rates of 26 non-vegetarian girls were determined, with the same apparatus and under conditions as nearly parallel as possible. Their average basal-metabolic rate was 4 per cent below normal.

Comparison of these results with the basal-metabolic rates of short-time vegetarians seems to show that a long period of vegetarianism is necessary if the rate is to be noticeably reduced.—Glen Wakeham and Louis A. Hansen, University of Colorado, *Science*, 74: 70 (July 17), 1931.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., PH. D., AND LEONARD GREENBURG,
M. D., PH. D.

Toxicity of Methyl Alcohol (Methanol) Following Skin Absorption and Inhalation—This is a progress report with a comprehensive bibliography and reference to a more extensive separate bibliography and concerns an experimental study of the toxicity of methyl alcohol using 265 animals, including monkeys, rabbits and rats. The materials for test purposes included crude, 95 per cent, and highly purified natural and also synthetic methyl alcohol derived from three sources of manufacture.

In the skin absorption experiments, the alcohol was applied under conditions that precluded inhalation. Methyl alcohol so applied invariably led to damage consistently like that arising from the oral intake of this substance. Methyl alcohol was likewise recovered on the distillation of all organs. The threshold of danger following skin absorption was found to be near 0.5 c.c. per kg. of animal weight, applied 4 times daily. It was found that 1.3 c.c. per kg. of weight will produce death within 48 hours, when such applications are made at the rate of 4 per day.

If these results obtained from monkeys may be applied to man, approximately 1 oz. (31 c.c.) of methyl alcohol repeatedly in contact with the human body, under conditions favorable to retention and evaporation, constitutes a threat to well-being.

Inhalation experiments were also carried out with the three kinds of animals mentioned, in concentrations ranging from 1,000 to 40,000 p.p.m. of methyl alcohol vapor. All of these concentra-

tions have produced death among exposed animals.

One thousand p.p.m. of air have killed some, but not all animals, the shortest exposure time being 41 hours, at the rate of 18 hours per day. Rabbits, and particularly black rabbits, are much less susceptible to the action of methyl alcohol than other animals. Marked variations in individual susceptibility have been observed.

An exposure of 1 hour daily to 40,000 parts of methyl alcohol vapor per million of air causes scant evidence of immediate impairment among animals, but eventually kills. Four hours of such exposure promptly kills all animals. It was also found that the inhalation of methyl alcohol has regularly yielded methyl alcohol on distillation of organs, blood, urine, muscle tissue, etc.

The threshold of danger by inhalation is well below 1,000 p.p.m. of methyl alcohol vapor. If this degree of toxicity obtained from monkeys applies to man, the vapors from 1 oz. of methyl alcohol entering the human body constitute a threat to life even when the exposure is distributed over 2 or 3 days.

A later publication will report details upon tissue pathology, although note is here made of extensive peripheral nerve damage.

On a basis of exposure, c.c. for c.c., methyl alcohol is at least as toxic through inhalation or skin absorption as it is following oral intake.

In view of the very small amounts necessary to produce dire clinical conditions and death in animals most like men, it is reasonable to assume that practical hazards for human beings may be produced under conditions of apparently trivial exposures.—

Carey P. McCord, *Indust. & Eng. Chem.*, 23, 8: 931-936 (Aug.), 1931.

The Health of Office Workers—

This paper was presented by the author before the Office Management Conference of the American Management Association, and considers, in Part I, the health status and needs of office workers in which the matter of the individual is discussed with relation to sex, age, term of service, marital condition, causes of sickness and death, and then with the matter of environment as related to size of community, the effect on health of the number of workers in office or building, the advantages and disadvantages of an office environment, ventilation, heating and lighting, and special working conditions pertaining especially to stenographers, typists, and comptometer operators.

Part II takes up suggestions for dealing with the health problems of office workers, considering the essentials of an industrial health program, the characteristics of the office worker group, importance of personal hygiene, and of pre-employment physical examinations.

Management's opportunities and responsibilities for the health of office workers are outlined under working conditions and environment, periodic health examinations, health supervision, health education, and medical and social service.

Certain relations of the American Telephone and Telegraph Company, of which the author is health director, are made under some of the above headings.

Three pages of discussion follow by T. O. Kennedy of the Ohio Public Service Company, John S. Shaw of the Hercules Powder Company, L. R. Frazier of the Dennison Manufacturing Company, Hanns Gramm of the Textile Machine Works, A. M. Boyd of the Philadelphia Electric Company, S. F. Shattuck of the Kimberly-Clark Corporation, R. O. Beckman of the Kroger Grocery & Baking Company, and by the author himself.—Leverett D. Bristol, American Management Association, Office Management Series: No. 48 (20

Vesey Street, New York, N. Y.), 20 pp., 1930.

Dust Hypersensitiveness with Special Reference to Castor Bean—

In the study of castor bean dust hypersensitiveness there is an especially interesting phase of the dust problem. The correlation with animal experimentation is also singular. A review of literature reports pertaining to this problem is given.

The occurrence of endemic asthma in a community, reported elsewhere, encouraged the author to make experiments, using guinea pigs. The results tend to support the hypothesis that an antigenic dust in a dry state can act as a sensitizing agent, and that entry into the body may be gained through the nasal mucosa. From this it is believed that dusts produced in industries may be significant factors in the production of certain respiratory sensitization afflictions.

Preventive measures, it is hoped, may eventually recognize the problem as stated.—Bret Ratner, *J. Allergy*, 2, 1: 3-7 (Nov.), 1930.

Domestic Carbon Monoxide Poisoning, 1931, Ohio Department of Health—

A summation of the carbon monoxide mishaps associated with gas-fired heating appliances, reported to the Division of Industrial Hygiene for the year July 1, 1930, to June 30, 1931, shows that there has been a considerable reduction in the number of fatalities this year from those of previous years. Last year there were 52 deaths. The average for the last 5 years is 44. This year there are 35 including 3 from unburned gas of which were 9 we have news-9 cases with 3 deaths, not in the above figures.

Space-heaters,

deaths, water heaters with 5, gas ranges with 6, and hot-plates with 3 deaths. Twenty-six cases with 6 deaths occurred in bedrooms, 14 cases with 8 deaths in living rooms, 16 cases with 5 deaths in bathrooms, and 21 cases with 5 deaths in kitchens.

Heaters in bedrooms and water heaters in bathrooms continue to be among the leading offenders.

A faulty water heater in a school basement was the cause of 13 cases, although there were no deaths. There were 3 cases reported due to gasoline water heaters, and 1 to a gasoline clothes press, with no deaths.

Among the general features, domestic users are asked to see that all gas heating appliances are properly ventilated. They should not be located in sleeping rooms. Water heaters should not be located in bedrooms or kitchens. Care should be taken to see that in case of gas ranges, the burners are located at a sufficient distance below the grids to prevent the inner blue cone of the flame from touching cold vessels or objects to be heated up.

There was a considerable increase in the number of deaths from auto exhausts. Out of a total of 98 mishaps there were 41 deaths as compared to 84 mishaps and 35 deaths last year. All the deaths occurred in garages. Five apparently were suicidal.

It is felt that too few auto drivers yet realize the chances they take when exposing themselves to motor exhaust fumes in closed garages.—B. E. Neiswander, Chief, Division of Industrial Hygiene, Ohio Department of Health, Typewritten Report, 5 pp., July, 1931.

Heart Disease and Mental Strain—Observant clinicians have frequently noted the tragic crises in cardiovascular cases, when a man is stricken, not from running for a car or climbing a flight of steps, or horseback riding, or dancing, but from some intensive strain in a di-

rectors' meeting or a business conference, requiring unusual concentration on problems involving great responsibility or intensive intellectual analysis.

Dr. Carey P. McCord at a recent meeting of the Association of Life Insurance Medical Directors presented the results of clinical investigations sponsored by The Heart Council of Cincinnati as to cardiac conditions in various types of employment. He said:

The concept that work is not a producer of heart and blood vessel degeneration is almost entirely linked up with excessive muscular work on a foot-pound basis, such as may arise in the ditch digger, the boiler maker, the football player, or the Olympic runner. It is granted that scant proof exists that such work leads to cardiovascular harm. On the other hand, there are forms of work, as well as other aspects of human life, that lead to continual trauma or indignities to the autonomic nervous system, that so influence the functions of visceral tissues as to culminate in organic changes. It is the thesis of this paper that the cardiovascular system may be organically involved in this process.

Referring to the particularly high rate of cardiovascular disease among train dispatchers, Dr. McCord says:

... We are prompted to believe, from all our findings, that portions of this unusual extent of organic cardiovascular abnormality are the results of prolonged, overwhelming mental strain—in short, *organic impairment from mental trauma*.

While it may be true, in a physical sense, that a healthy heart cannot be strained, we are inclined to believe that this is not the case in so far as the autonomic nervous system is concerned. With blood pressures and pulse rates responding quickly to psychic factors, there exists a situation in which mechanical disturbance can supervene and do actual physical damage.—*How to Live*, 14, 7: 1-2 (July), 1931.

E. R. H.

The Subjective Side of Fatigue in Industry—A large public utility cor-

poration invited the writer to devote a whole year to the observation of a group of normal workers of various occupations, ages, personality types, and nationalities. They were very carefully examined physically and followed through the year both at work and at home in the case of 12 men, while 5 others were studied with the same care for periods of several months, and over 100 workers were included at one time or another in some phase of the fatigue study. It was found that plant factors and non-plant factors could be weighted and compared in causation of fatigue, also that measures for reduction of the plant factors could be reasonably prescribed.

There is still needed the discovery of scientific methods of detecting a harmful amount of fatigue. Usually the feeling of tiredness coincides with true fatigue, though this is not always the case. Boredom and the feeling of tiredness may both be the result of a mental or emotional attitude. To feel tired more than one-fifth of the waking time is suggestive of an unwise environmental strain or of organic malfunctioning. Tiredness should also occur irregularly both during the day and over longer periods.

The outside activities including efforts at recreation, family duties, and sleep habits are the most important causes of fatigue. All told, the employer would seem to be able to reach only half of the causes of fatigue by direct methods, but can lead in attempts to reduce the effect of the non-plant causes. Among these latter causes, the woman is all important; for she, whether wife or sweetheart, is the most powerful stimu-

lus of the outside factors. Therefore, wise education of the women in sane living in the broadest aspects will become the most powerful controlling factor.—Rex B. Hersey, *J. Indust. Hyg.*, XIII, 6: 185–203 (June), 1931.

E. R. H.

Arsenical Poisoning—Several cases of arsenical poisoning of industrial origin are reported: (1) enamelling bathtubs with a glaze composed of arsenic-lead vitreous enamel; (2) enamel fusing of the preceding vitreous enamel for 3 months; (3) brass moldings, mostly scrap metals—slightly affected; and (4) furnace hand, brass molding—slightly affected. In the case of brass molders, old gas fittings were suspected as the source of the arsenic.

The proof of these cases was determined by the examination of the hair and nails. The analysis of the urine in such cases is often of little value. Arsenic in the hair ran from 1 to 8 mg. per 100 gm. Arsenic in the nails was found to the extent of 9.2 mg. per 100 gm. In the case of a sprayer using a solution of sulphuric acid and arsenic for 10 days and developing severe peripheral neuritis, 33.5 mg. of arsenic per 100 gm. were found in the hair, and 160 mg. in the nails, at a time of 79 days following the last exposure.

Arsenic was found in the urine in the first 4 cases above mentioned in amounts ranging from nothing up to 0.16 mg. per l. and at a time following the last exposure from 1 to 60 days.—Charles Badham *et al.* Report of the Director General of Public Health, New South Wales, for the year ending 31 December, 1929.

CHILD HYGIENE

RICHARD A. BOLT, M. D., DR. P. H.

HEALTH OF THE PRESCHOOL CHILD

THE preschool age can no longer be looked upon as the neglected period of childhood. Since the publication in 1923 of *The Preschool Child*, by Arnold Gesell, and *The Health of the Runabout Child*, by William Palmer Lucas, a tremendous amount of interest has been aroused in the physical, mental, and social development of the child from 2 to 6 years of age. A great deal of valuable data has been assembled from researches carried on in connection with institutes of child welfare. The growth of the nursery school movement in this country also has added to our knowledge of the preschool child. Studies carried on by various committees of the recent White House Conference on Child Health and Protection give us a new basis upon which to proceed in our endeavors for the health of the child before school entrance. It may truly be said that we have accumulated enough knowledge to protect the health of the child of preschool age, if only we could find ways and means of applying it to the individual child.

The importance of the preschool age can scarcely be over emphasized. The first year of life has problems peculiar to itself, which have been attacked vigorously during the past 20 years. That we have met with measurable success is indicated by a cutting of the infant mortality rate practically in half. Present-day problems center about maternity, early infancy, and the preschool years. Aside from the first few months of life, the preschool age is one of relatively low mortality and high morbidity. Considerable damage is done during this

period, the child suffering from many defects which may not become evident until later in life. This is a period of rapid growth and development, which creates problems concerning nutrition, immunity and resistance, posture, etc. Many new environmental adjustments are necessary. It is well known that the child is highly susceptible to the infectious diseases during the preschool years. Our efforts for prevention, therefore, should be centered upon this period. Measles, whooping cough, diphtheria, and scarlet fever take their greatest toll before school entrance. The young child is very susceptible to these and other diseases, which do not necessarily kill the child, but may leave it with serious defects of the eyes, ears, heart, kidneys, or lungs. Crippling during childhood is due largely to injuries at birth, poliomyelitis, tuberculosis, and accidents.

The period under consideration is one in which the child becomes rapidly socialized. In its wider contacts it is exposed to many physical, mental, and moral hazards. This is an age of death dealing and disabling accidents, a considerable number of which are readily preventable. Accidents have assumed greater and greater importance as a cause of death and crippling among children of preschool age. In the earlier years many of them take place in the home environment and in the later years on the streets and public highways.

We recognize definitely now the childhood type of tuberculosis. It results usually from contact with tuberculosis in the home environment. If we could

recognize it early and place the child under proper supervision, we could largely control tuberculosis in children. The problem during school age would not be so serious as it is now. The main factors of tuberculosis in childhood have been discussed in the July issue of this JOURNAL.

Psychiatrists now tell us that the years before school entrance are those in which many habit and behavior difficulties arise. These offer a wide field for proper guidance and mental hygiene. If we could correct the early disorders of personality and the emotional upsets arising in children before school age, it is certain many of the problems of delinquency could be solved more readily. Proper technics in handling behavior problems have been worked out in our child guidance clinics. A considerable mass of valuable material derived from case studies in these clinics is now awaiting application to the preschool child.

It should be borne in mind that the child hygiene movement of the past two decades has made it possible to save more children, who now are living in the preschool and school years. While the birth rate has declined in recent years, it has not affected appreciably the number of children coming into the upper age groups. Our problem for the preschool child, therefore, assumes a quantitative as well as a qualitative aspect.

The program we adopt for the health of the preschool child depends upon its basic needs prior to school entrance. These are plainly evident. The question arises how best the needs may be met through individual or organized health and social work of the community. Modern scientific methods in medicine, education, and social welfare should be made available to every child. These methods include:

1. *The extension of regular systematic health examinations* with which we are so familiar in infant welfare. These should be conducted by a pediatricist or physician skilled in handling

children and interested in preventive medicine. This has been made possible for the infant by means of infant welfare centers as a part of community health centers.

Coöperation with the home is essential. In many places measures have been taken to bring this about through the parent-teacher associations, women's clubs, day nurseries, and kindergartens.

2. *The protection against the communicable diseases by immunization* against those for which we have adequate measures, such as smallpox and diphtheria. Suitable quarantine should be carried out in all cases. Popular education of the parents as to early signs and symptoms of the communicable diseases is desirable, and the social responsibility to keep sick children isolated from other children should be stressed.

3. *The promotion of good nutrition* Malnutrition often begins in this period from bad habits of eating, unwholesome or poorly balanced diets, and over-stimulation. There is no question but that a large amount of malnutrition in early school life has its beginning in the preschool years.

4. *The prevention of heart disease in childhood.* This also is a preschool problem. The control of the acute infectious diseases, chronic tonsillitis, focal infections, and rheumatic fever undoubtedly would do much to reduce the incidence of heart disease. As a matter of fact, there is evidence which leads us to believe that heart disease during the preschool years is decreasing, due to better control of the communicable diseases.

5. *Mouth hygiene should begin early in life.* In the preschool period the jaws and teeth are assuming their permanent form and structure. Aside from prenatal hygiene for the mother, these years afford the best possible time in which to begin oral hygiene. Modern research indicates that adequate diet for the mother during the prenatal period and freedom from infectious diseases condition the developing teeth. Suitable feeding coupled with periodic dental care assures the greatest protection for the newly formed teeth.

6. *The promotion of well tried safety measures for the benefit of children.* Instruction in safety-first should begin early in the child's life and continue up to adult years. Much has been accomplished in some places by proper instruction in the nursery schools and kindergartens. The schools themselves have been a great factor in the safety-first campaign. In some cities the junior safety squad has rendered excellent service in preventing accidents in the neighborhood of the schools.

7. *Mental hygiene and child guidance.* Opportunities should be afforded, through child

guidance clinics, day nurseries, and kindergartens, for the observation and guidance of young children, especially those exhibiting deviation from the normal. This is the period in which social maladjustments begin. It is the ideal stage to inculcate good habits and influence character building. Parents should be given the best possible information and instruction to meet conduct difficulties. Expert diagnostic facilities should be available. A better correlation and extension of all the facilities in the community to meet the mental hygiene needs of the child should be worked out.

With these needs of the preschool child constantly before us and with the scientific methods of approach in our hands, the next step to determine is the availability of community resources. In almost every city one or more of the following facilities already are available and others could be established readily:

1. The medical and dental professions.
2. Local health centers in which work for the preschool child is integrated with other phases of the child health program.
3. Public health nurses and visiting nurse associations.
4. A bureau of child hygiene of the local health department, operating through child welfare centers, children's clinics, and dispensaries.
5. Nursery schools, day nurseries, and kindergartens. The educational facilities of the

kindergartens and of the nursery schools lend themselves very favorably to preschool hygiene.

6. Child guidance clinics.

7. Parent-teacher associations. In many places parent-teacher associations have taken the initiative in securing coöperation between the schools, the medical profession, and the local health department in providing preschool examinations.

8. Municipal and school playgrounds.

9. Parental and pre-parental education.

In most places the main problem seems to be not one of lack of adequate facilities, but of community organization to facilitate a coöperative plan whereby each organization may contribute its special work for the good of the whole. Representative group consideration and decision upon the local problems concerning the preschool child are essential. Minimum standards for the health of the child should be determined, based upon scientific procedures and well tried methods. An attempt should be made to have these essentials carried out through the various local organizations, making use of existing facilities. A careful study and analysis of all data pertaining to the preschool child in each locality should be made, and a comprehensive program laid out to meet the needs.

REPORT OF A PRESCHOOL AND INFANT WELFARE CLINIC

DR. E. V. THIEHOFF, Chief of the Child Hygiene Service of the City Health Department in Akron, O., recently prepared an informative report of the work accomplished at the preschool clinic in that city.

At the beginning of 1929 the City of Akron, O., annexed the suburban town of Kenmore, with an approximate population of 15,000. The Akron City Health Department immediately proceeded to institute a preschool and infant welfare clinic to serve that district. Since that time a 2-hour clinic has been held twice a week. Nursing service is provided

for the clinic by the Division of Public Health Nursing of the City Health Department. There is 1 station nurse with 1 assisting nurse in the clinic. One physician is in charge.

The nurses do the clerical work, taking the case histories, and also weigh and measure the children. The station nurse assists the physician in the examination and attention given the clinical patrons.

Emphasis is laid upon the fact that this is a clinic for well children. Parents are urged to take children who are ill or have physical defects to private physicians or to other agencies. The purpose is to keep the child well. No treating is done in the clinics, but all cases needing medical attention are referred

to the private physicians, or in indigent cases to hospital dispensaries.

Immunization against smallpox and diphtheria is offered to those who cannot or would not go to a private physician. Children are accepted in the clinic up to school age (6 years). . . . When they reach school age they are dismissed and transferred to school records. . . .

The report covers the period from February 28, 1929, to February 28, 1931. Thus we find that after 2 years, 424 out of the 827 children, both infants and preschool children, who have entered the clinic are still active. This is approximately 50 per cent. . . .

The clinic serves a district with a mixed national population with relatively few colored people. In the majority of cases there are only three or four members in the families represented. The largest number of fathers are classed as skilled laborers. Most of these work in the rubber and tire factories. Their average annual income is \$1,500. Due to the current depression there are quite a number who are unemployed and have been for some time. It will be noted that most of the mothers are housewives, but few being employed outside of the home. . . . The large majority of cases have their private physician to whom they go for any medical attention or

service. The name of the family physician in each case is kept on record and if need for medical service arises, the patron is immediately referred to that doctor . . .

Out of a total clinical attendance of 3,655 infants and preschool children for the 2-year period under consideration, there has been an average weekly attendance of 35 plus or approximately 18 children to a clinic. . . .

The number of correction of defects secured as compared to the number found is very small. This is in part due to the fact that many clinical patrons move or become inactive before correction of defects is secured. There are many children who need correction of defects but their parents cannot afford such and charity demands on local hospitals have been so heavy that the hospitals cannot begin to meet all the needs. Undoubtedly this matter of securing correction of defects is a weak factor in the clinic.

The station nurses make home visits not only to urge correction of defects but also to advise the parents as to the care of the children. It will be noted that they have made a large number of such calls, especially when one considers that their work is not confined to the clinic but that they do school and public health nursing service in general.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

The Milbank Memorial Fund Aids Nursing Education—All groups interested in the improvement of public health administration are emphasizing the need for better trained personnel. The Milbank Memorial Fund knowing that the rôle of the public health nurse is one of growing importance in both official and unofficial health organizations has for some time been interested in better training for public health nurses. Three public health nursing

projects are at present being assisted by the Fund.

RURAL NURSING SCHOLARSHIPS

Since 1926 the Fund has offered scholarships for rural field experience for students from the Nursing Education Department in Teachers College, Columbia University. The scholarship allowance is large enough to provide transportation and living expenses for 2 months in Cattaraugus County where the health department is organized on a county unit plan, thus enabling the student to have experience as well as ob-

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

servation in a generalized public health nursing program.

By the end of the summer of 1931, 17 nurses will have had this field experience. With one or two exceptions all of the nurses who have completed this course are engaged in public health nursing.

THE TEACHING SERVICE OF EAST HARLEM NURSING AND HEALTH SERVICE

In 1928 the Milbank Memorial Fund made a special grant which initiated the teaching program of the East Harlem Nursing and Health Service because field experience was needed for advanced public health nursing students. Here the teaching staff is of university caliber and maintains high standards and technics.

Three hundred ninety-seven students have been enrolled in this educational service in the last 37 months. They represented 36 states and 30 different countries. Nearly half of the students came from the Department of Nursing Education of Teachers College, Columbia University. Thirty per cent of the enrollment comprised nurses from other health organizations in New York, and 22 per cent registered through an affiliation with the Rockefeller Foundation. Most of these latter were from foreign countries.

In addition to these there were 113 "visitors" who spent an average of between 3 and 4 hours in group classes and individual conferences.

DEPARTMENT OF PUBLIC HEALTH NURSING, SYRACUSE UNIVERSITY

This course was described in these notes in the April, 1931, number of the *American Journal of Public Health*.

There are two programs of study offered properly qualified graduate nurses at this university: one leading to a degree of B.S. with a major in Public Health Nursing; the other leading to the certificate in Public Health Nursing.

Supervised field experience is offered

in addition to the theory, through the coöperation of the Syracuse City Health Department Bureau of Nursing, the Visiting Nurse Association, and the School Health Service of the Board of Education.—From the *News Digest* in the *Milbank Quart. Bull.*, July, 1931, pp. 142–144.

First Aid Instruction for Nurses—Many graduate nurses have found, when faced with the necessity for administering first aid far from the reach of physician and hospital, that the nicely applied spiral reverse bandages at which they were so adept in student training days have little place in the emergencies of motor, camp and industrial accidents. As nurses have entered the broader fields of public service, industrial nursing and health instruction, they have found themselves wholly unprepared to administer or teach anyone else to administer the simple first aid procedures. It has been a large task for the public health nurse to prepare herself so that she might teach first aid to 4-H Clubs and scout groups, which are increasingly demanding such instruction.

An article in the *Red Cross Courier* of July, 1931, with the title "Student Nurses Grounded in First Aid," shows a recognition of the need for more intensive first aid instruction for nurses and relates a practical way of meeting the need:

For the last 4 years the senior classes in every school of nursing in Columbus, O., have been instructed in the Red Cross standard first aid course. Dr. Drew L. Davies, Chairman, First Aid and Life-Saving Committee of Franklin County Chapter, who gives the instruction, points out that the enrollment of these student nurses is one of the most potent influences in the extension of this service. . . . Mr. Davies said:

"From the receiving rooms of many of the Columbus hospitals comes the interesting information that there is a

decided improvement in the condition of accident patients when they are brought in, due to treatment having been rendered by Red Cross first aiders."—*Student Nurses Grounded in First Aid, Red Cross Courier*, XI, 1: 405 (July), 1931.

Medical Social Service Versus Public Health Nursing—The California State Board of Health held one of its examinations for public health nurses in May. One of the girls who received the highest grade in the written examination answered the question as to how medical social service differs from public health nursing as follows:

Medical Social Service

- (1) Determines eligibility for care at public expense.
Cases may be referred to medical social worker from other social service worker or case worker.
- (2) Assists patients to settle economic and family problems in order to enter hospital to receive proper care.
Helps patient in hospital by helping settle family and business affairs.
- (3) Follows cases after patient goes home.
Helps patient make adjustments to his health and limitations. May sometimes locate contacts or sources of infection of disease.

Public Health Nursing

- (1) Refers to clinic or hospital for care at public expense.
Finds cases in field and persuades patient to apply for needed care.
- (2) Almost no work done in hospitals now.
Prevention could be done—child welfare taught in maternity and pediatrics wards.
- (3) Makes home visits and helps patients in health problems. May do much to prevent a relapse and assist in normal recovery. Sees that doctor's orders are being carried out.
May also advise economically and do same type of work done by medical social worker in mental hygiene and general advice.
Watches contacts and helps prevent communicable disease.

—Questions and Answers in Public Health Nurse Examination, *Weekly Bull.*, Calif. State Dept. of Public Health, June 20, 1931.

At Last! Some Research Work in Public Health Nursing—The Board of Directors of the Commonwealth Fund recently made a grant of \$25,000 to the National Organization for Public Health Nursing to finance a study of the present administration and practice of public health nursing.

The N. O. P. H. N. has developed qualitative and quantitative standards in reference to public health nursing, and they have been generally accepted as goals, but it is not known to what extent these standards are in actual operation over the country. An evaluation of the present development of public health nursing as measured by these standards may reveal that some of the standards themselves need revision.

The study will be made in different sections of the country and will cover both rural and urban services under both official and non-official administration.—*Good News, Pub. Health Nurs.*, XXIII, 8: 399 (Aug.), 1931.

The Public Health Nurse and the Partially Seeing Child—Public health nurses, particularly those working in rural districts, have hard problems with the child having eye difficulties. Even after they have succeeded in getting eye defects corrected and eye diseases under treatment, what can be done with the child whose eye troubles are so serious that after everything possible has been done, he cannot see well enough to use the equipment provided?

Oftentimes nurses think this type of child belongs in a school for the blind, when he really belongs with seeing children, because he will naturally use the little sight he has left to learn, instead of switching to the sense of touch entirely.

Teachers of partially seeing pupils in schools for the blind are the first to recognize that in unsupervised periods these children will use their eyes, since sight is their natural mode of approach to the brain, and that the reading of raised dots with the eyes is far more harmful than reading ink print, because there is no contrast to help the eye in distinguishing the letters.

The White House Conference report showed that partially seeing children in 13 states were sent to a school for the blind, and that not rarely these children were placed in classes for the mentally deficient, because here they would receive more attention. State authorities say these children are sent to blind schools because there is no other place for them.

But why not make a place? Twenty-three states have already done so, by establishing sight-saving classes in the public school systems of the leading cities. A public health nurse in any large city can ascertain whether such classes have been established. If she is fortunate enough to be in a city so advanced educationally, her problem of the placement of the partially seeing child has already been solved for her. If there is no such class, her problem should become the problem of the community and perhaps her very effort in relation to this particular charge may be the starting point for giving the educational advantages of a sight-saving class to all in the community who may need them.

What can the small town or rural nurse do for the partially seeing?

1. She may arrange for a child to go to the nearest city in which a sight-saving class has been established.

2. She may interest nurses in other communities to discover these children

in their districts and persuade the education authorities to establish a county class which all these children may attend.

3. If the region is too remote the teacher in the rural school can be given educational media like those provided in sight-saving classes; but this is not a very good solution, as the teacher to be effective should be thoroughly trained in this type of work. However, if given individual help she can do a great deal.

For success in this venture, however, several attributes are necessary: first, a knowledge of the child's eye condition; a progressive myope offers quite a different problem from a child with static low vision. In the former instance it may actually be a matter of saving sight; in the latter, merely a matter of providing the means for an education. The second requisite is a teacher willing to undertake this work and with sufficient intelligence to be able to apply the help given. The third requisite is the necessary equipment.

A knowledge of the eye conditions may be difficult to acquire. It may mean taking the child quite a distance to an oculist for an examination, or it may be that advantage can be taken of a travelling clinic, federal or state. Indeed, such a case may be an entering wedge for the nurse to obtain the advantages of such clinic for her community.

The National Society for the Prevention of Blindness, 450 Seventh Avenue, New York, is always willing to render any assistance it can. Write there for help and information.—Winifred Hathaway, Protecting the Partially Seeing Child, *The Red Cross Courier*, XI, 2: 425, 426 (Aug.), 1931.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

For Readers Outside of North America—Experimentally, a special service is offered to readers in countries outside of North America. Their requests written on letterheads or business cards, accompanied by a money order for the equivalent of 2 cents postage for each request, may be sent to the editor of this department, who will forward the requests to the different publishers or organizations.

A card or letterhead for each separate publication or other sample; on the card the title or description of the item desired; the date of the JOURNAL in which the item was mentioned in this department of the JOURNAL. For periodicals not issued by health organizations and for publications sold at a specific price the order should go direct to the publisher.

"Mr. Average Healthy Citizen"
—Something to read before we make another health talk or write another folder on a health topic: "Science and Health: A Prescription for Cultivating Sales Resistance," by E. P. Lyon, dean of University of Minnesota Medical School. *Survey*, 112 East 19th St., New York. June 1, 1931. 30 cents. What is the "scientific basis" of health; how "health is automatic"; what the individual should know; the "doctrine of chances"; what one need not know; what not to read. "Science is knowledge. Science should make you bold, set you free."

Of course there is much here that you

will reject—but other parts may lead you to check the actual, practical significance of your teaching.

Health Education by a State Medical Society—The Illinois State Medical Society maintains an Educational Committee office at 185 North Wabash Avenue, Chicago. This committee gives a unique service in the field of health education to county medical societies and lay organizations.

Speakers' Bureau: Physicians, members in good standing of the Illinois State Medical Society, are scheduled to present popular health talks before lay groups. The speakers come without any expense to clubs and schools, but the committee does request that at least 3 weeks' notice be given when asking for health programs.

The following list of subjects has been suggested for health talks during the year, September 1931–1932:

Men's Clubs—Financial Values of Health; The Business Man and His Stomach; Disease Prevention and Health Preservation; Physical and Mental Health; Animal Experimentation in Relation to Human Welfare; What Everyone Should Know About Cancer; Health vs. Business Inventories; Physical and Mental Health.

Women's Clubs and Parent-Teacher Associations—Health Problems in Illinois; What Every Woman Should Know About Cancer; Health Inventories; Physical and Mental Health; Our Duty to the Child in Prevention of Communicable Diseases; Preparing the Child for Adolescence; The Parent and Child Relationship; Medical Science

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Protects the Child; Animal Experimentation in Relation to Human Welfare; Prevention of Disease.

High School Assemblies—Our Debt to Medical Science (story of some famous scientists); Some Important Phases of Health; The Story of Infections; Health Lessons Learned from the World War; X-Ray and Radium: What Every High School Boy and Girl Should Know About Cancer; Health and Happiness.

Radio: Radio talks are given from stations WGN, the Chicago Tribune, every Tuesday morning at 11:50 o'clock, and from WJJD, every Monday, Wednesday and Friday noon at 11:45 o'clock, daylight saving time. The talks cover health subjects of current interest and are a popular feature of the work of the committee.

The Chicago Pediatric Society and the Educational Committee also sponsor a period for young mothers from radio station WJJD at 11:15 o'clock, daylight saving time, every morning. During this 10-minute period, talks of special interest to mothers are broadcast.

Press Service: Press material on health subjects of value to local communities is supplied to newspapers for use over authority of the county medical society or the Educational Committee.

Upon request, special educational articles are prepared on diseases which may be prevalent, or material for diphtheria immunization campaigns, smallpox vaccination campaigns, Summer Round-Up.

General Service: Health poster exhibits loaned to schools and clubs.

The committee does not own moving picture films or projectors, but will secure loan of films and slides from other sources.

Package libraries on health subjects available.

Health folders and literature secured for distribution.

County and city superintendents of schools, women's clubs, men's clubs, parent-teacher associations and all other civic groups are invited to make use of the above services offered by the Educational Committee.

Why One Weekly Bulletin—Detroit issues weekly a bulletin of one or more multigraphed letter-size sheets. It is not popular, but is explanatory and interpretive as to statistics and Department plans and policies. By request Dr. Henry C. Vaughan sent the following:

Our *Weekly Health Review* was designed primarily as an exchange letter between the Detroit Department of Health and the health departments of the neighboring large cities, as well as state health departments. It was created during the time of the influenza epidemic. We found that the statistical information on the prevalence of disease received through the U. S. Public Health Service was too old to be of any particular value to us and we therefore established our own means of keeping informed of epidemic conditions in large neighboring communities and designed our *Weekly Health Review* so that our neighbors might be informed of the situation in Detroit, and likewise so that we might keep the physicians of Detroit informed.

The *Weekly Health Review* is published each week in the *Bulletin* of the Wayne County Medical Society and thus reaches virtually all physicians of Detroit each week. It is also released to the daily papers and is generously drawn upon by these papers as well as the foreign language papers.

Our mailing list grew to the neighborhood of 1,000 but in the interests of rigid economy we have cut this down to approximately 300, which, added to the 1,500 copies sent to physicians through the County Medical Society, makes an issue of 1,800 to 2,000 per week.

A Study of the Market for Health Information—A study was made by the Department of Health, New Haven, Conn., during the summer and autumn of 1930, with the hope that it might add its bit to the present information relative to the worth of booklets and perhaps suggest additional methods of investigation to others.

For this study a health booklet was selected toward which it was possible to take a neutral attitude: "Hitch-Hikers," put out by the Cleanliness Institute, which contains 57 pages of printed material and pictures. The intent of the booklet was to instruct the public in the need of cleanliness in preparation and handling of foods, milk, water, etc. A variety of classes of individuals have been exposed to this booklet and their reactions recorded. Several methods of distribution were used and their effectiveness graded.

The plan followed was divided into two parts. In the first people of different classes, such as householders, motor car drivers, students, library visitors, store customers, bank patrons and policemen, were exposed to a copy of this booklet which contained a brief questionnaire entitled "Help Wanted," and a prepaid addressed return envelope. The responses were classified as to volume and character.

In the second part, not included in this summary, the booklet was presented to groups of medical students, nurses, health workers and high school pupils, without a questionnaire but with the request, and in some instances a demand, that they give their reaction to it.

In part one of the study the questionnaire was so prepared as to present a neutral point of view and so fashioned that answers would be brief. By the questions "Did you pass this copy on to anyone else for their information?" and "If there are any to whom you would like a copy of Hitch-Hikers sent, give their names, etc.," it was hoped to get additional data as to the reader's idea of its value.

A total of 3,475 copies of the booklet were distributed. One thousand were distributed to homes which included those of the rich and poor, the high class residential sections down to the tenement house. Each contained the questionnaire and prepaid return enve-

lope. From this group 30 replies were received.

In parked automobiles in the center of New Haven and also in the outskirts of the city 1,000 were distributed. The booklets were left in unoccupied automobiles, the distributors having been instructed to place them carefully on the seats. These also contained the standard questionnaire and the return envelope. From this group 34 replies were received.

At central points around Yale University campus on the morning of the Yale-Georgia football game 300 copies were distributed. Booklets were left in the Yale Post Office, in the Athletic Association's ticket office, and other places including the Dean's Office, and Divinity School Library. Sixteen replies were received.

In the New Haven Free Public Library 250 copies were placed for distribution. These were arranged on a table in the lobby through which all entering or leaving had to pass. Beside the booklets was placed a sign "Health Bulletins—For Adults Only."

During the period these booklets were on distribution in the Library a special check-up was made from 3 to 4:20 o'clock on one afternoon, which showed that 5.1 per cent of those passing the table took copies of the booklet while 8 per cent looked at but replaced it. Of the 9 who took booklets during this special check only 1 reply was received. Of the number taking booklets during the period the booklets were available in the Library, 41 sent replies.

Two hundred copies were placed in a leading New Haven department store. A small card invited patrons to "Take One." Ten replies were received. Two hundred copies left on the desks and counters of several banks where they could be picked up by patrons brought fourteen replies. From 200 copies distributed to members of the police force 5 replies were received.

One hundred and twenty-five copies were distributed by an usher on the opening night of the season at a large New Haven playhouse. The production was "Mr. Gilhooley." The audience showed reluctance in taking the booklets and of those who did, the larger number left them on the seats when the performance was over. Six, however, were interested sufficiently not only to take the booklet home with them, but to answer by mail. One hundred copies were left on a counter in the Yale Co-operative Shop, frequented largely by Yale students, for free distribution. Three replies were received.

The returns show that the Library visitors took the proposition the most seriously. The per cent of replies was as follows: Library, 16.4; Banks, 7; Yale Campus, 5.3; Y. W. C. A., 5; Department Store, 5; Theatre, 4.8; Automobiles, 3.4; Homes, 3; Yale Co-op Shop, 3; and Police Stations, 2.5.

An analysis of these 164 replies is presented in the following table:

Question	Replies	Per cent of total replies
Did the cover attract your attention, etc.?	yes 144	87.8
	no 11	6.7
	blank 9	5.5
Did you read book from beginning to end?	yes 102	62.2
	no 59	35.9
	blank 9	1.8
Did you read part?	yes 59	35.9
	no 105	64.1
Is the booklet worth reading?	yes 155	94.5
	no 5	3.0
	blank 4	2.4

Additional questions: Has it value in teaching health? Which was most interesting: Picture or text? Did you pass booklet on to another? Requested additional copies for others?

—JOHN L. RICE, Health Officer

How Would You Do It?—There can be little question of the need to know more than we do about the mar-

ket for health advice put up in folders and booklets for free distribution.

Dr. Rice reports on a study carefully planned and carried through with equal care which offers some interesting evidence on the reception given a single pamphlet under varied conditions. What do you think of this study? We should like to use it as clinic material for a discussion in these columns of this important problem of testing the value of educational material.

Do you think 164 replies from a distribution of 3,475 copies is good, fair, or unsatisfactory? Does the comparison between returns from different methods of distribution offer a trustworthy guide to future distributing methods? What do you think of the questions asked of the readers? What other methods of testing interest in health literature do you know about?

POLIOMYELITIS

The following material in the files may be drawn upon another year.

"Blood Wanted to Aid Paralysis Victims," by Thomas Parran, Jr., M.D. New York State Dept. of Health. Aug. 5, 1931. Radio talk. *Free*.

"General Recommendations." New York State Dept. of Health. Press release. Aug. 12, 1931. *Free*.

"Infant Paralysis," by S. W. Wynne, M.D. Dept. of Health, New York, N. Y. Aug. 10, 1931. Radio talk: "there is no epidemic"; reasonable precautions. *Free*.

"Poliomyelitis," by D. C. Steel-smith, M.D. Iowa State Dept. of Health. Press release. *Free*.

"Treatment of Poliomyelitis." *Weekly Bulletin*, Dept. of Health, New York, N. Y.

MAGAZINE ARTICLES

"The Crisis in Medical Service," by R. L. Duffus. *Harper's*. Sept., 1931.

"Feeding the Finicky Child," by H.

L. K. Shaw, M.D. *Herald-Tribune Magazine*, New York. Aug. 16, 1931.

"Getting the Children Ready for School," by Dr. W. R. Ramsay; "The School Lunch," by M. K. Ray. *Farmer's Wife*, St. Paul. Sept., 1931. *Copy free*.

"Vitamin's Place in the Home," by R. E. Wadsworth, M.D. *Collier's*. Aug. 15, 1931. "They have been rebuked—and with good reason."

THEY BELIEVE

In a discussion of "Trends in Nursing Education" (*Am. Journal of Nursing*. May, 1931):

But however nurses may have failed in presenting their needs and problems in alluring and convincing fashion, you will agree, I think, that this business is not entirely up to them. It is the public which is most vitally concerned in this whole question of nursing education and it is the public which suffers most when any system of education fails to function at its best. . . . Somehow the public must be made to face this question and to see that nursing schools need the same kind of public support which is given to normal schools or to agricultural colleges.

NEW

Industrial Health Digest (formerly *The Stethoscope*), Natl. Safety Council, Chicago.

The Commonwealth Bulletin, issued by Minneapolis Health Council, Citizens' Aid Bldg., is now issued jointly with the Minneapolis Division of Public Health.

Bulletin, Massachusetts Soc'ty for Social Hygiene, 1150 Little Bldg., Boston. 4 pages monthly—from March, 1931. Pleasing rough finish paper.

HONORABLE MENTION

To Massachusetts Dept. of Public Health: for dating numerous health education leaflets and folders.

To Trenton, N. J., Bureau of Health; New Brunswick, Canada, Dept. of Health; Hygiene Institute, LaSalle, Ill.: for table of contents in annual reports.

DEPRESSION AND DROUGHT

"A Health Program for Missouri's Drought Area," by Dr. James Stewart. *Missouri Public Health News*, State Board of Health, Aug., 1931.

"If Winter Comes," Community Fund, Minneapolis. 4-page folder on emergency need for visiting nurse and infant welfare services.

DIPHTHERIA

"Stagecoach Days," 4-page folder by Racine, Wis., Health Dept., shows that science "has progressed beyond the stagecoach days" and that diphtheria is now curable and preventable. The cover-page and other silhouette illustrations are by Mrs. Health Officer Bauer.

"Sorry But the Supply Is Exhausted"—That is the reply you may receive if you delay in writing for samples of various pieces of printed matter or other items mentioned on these pages.

Please lay aside some copies of your material mentioned here so that you have them for JOURNAL readers who will write for copies.

Again it should be mentioned that only single sample copies of most publications will be available. So don't ask for *free copies* for distribution except in the case of insurance companies and a very few other publishers. Some of the items listed will be supplied in quantity at reasonable prices.

Again, also, write direct to the publisher, the health department or other address given.

BOOKS AND REPORTS

American Physicians and Surgeons.

A Biographical Directory of Practicing Members of the Medical Profession in the United States and Canada—Edited by James Clark Fiffeld. Minneapolis: Midwest Company, 1931. 1,737 pp. Price, \$30.00.

This ponderous volume of 1,737 pages "is offered as a biographical directory of contemporary members of the medical profession, who are, at the time of going to press, in active practice in the United States and Canada, and who, by reason of their high attainments, skill and reliability, are especially entitled to inclusion in such a book." As far as it goes, the work has been done well, but there are many omissions which detract from its value. The foreword acknowledges that the work does not include all of the best physicians and surgeons in each place and recognizes that there will be criticism of some of the omissions. It states that many excellent members of the profession will not be found listed "because although their skill and reputation are unimpeachable, their duration of practice has not been considered sufficient." These statements do not seem to us to hang together. If the skill and reputation of a man are "unimpeachable," we do not see why length of practice should be considered.

It is manifestly impossible for any one doctor to know the names of all the physicians in the United States and Canada, and to determine their standing, so that a reviewer must select certain places with which he is familiar. Such a study brings to light omissions for which there seems to be no reasonable excuse, especially as the editor claims to have had "traveling repre-

sentatives, especially trained for such work," who "have made personal investigations as to the standing and repute of doctors in each locality," the final decisions being "based on a decided weight of opinion of the doctors themselves." Who these doctors were is not told.

The listing of hospitals is perhaps somewhat more complete, yet even in this we find some curious omissions. For example, in one town which has two hospitals, both of them approved for standardization by the A. C. S., one is mentioned, and the other is not.

The value of a directory depends upon the completeness and the justice with which the selections have been made. As said above, the book will prove of some value as far as it goes, but anyone who expects to find in it a fairly complete guide will be disappointed.

The printing and make-up are excellent.

M. P. RAVENEL

Kompendium der sozialen Hygiene

—By Prof. Dr. B. Chajes. (3d ed. rev.) Leipzig: Fischer's Medizinische Buchhandlung, H. Kornfeld, 1931. 167 pp. Price, bound, M. 11.40.

The progress in social hygiene in Germany, though halted at present by economic conditions, has been such as to command attention throughout the world. This third edition of Dr. Chajes' compendium is a brief but very useful handbook of German practice in the fields of medical statistics, nutrition, clothing, prevention and control of tuberculosis, sexual diseases, alcoholism, child hygiene, industrial hygiene (in-

cluding women's labor, child labor, home work, occupational risks, hours of labor, dust dangers, accident prevention, industrial poisonings and infections), the legal protection of employees (including state supervision, health, accident, invalid, old age, and unemployment insurance), eugenics; and federal, provincial, and community hygienic organizations. CHARLES A. KOFOID

Analogy and Medicine. *A Series of Brief Essays on Popular Medicine—By Louis R. Effler, M.D. Toledo, O.: Published by the author, 1931. 260 pp. Price, \$3.00.*

This little volume is of the same general type as *Three Minute Medicine* by the same author, which we have already reviewed favorably in these columns. It consists of 103 short essays covering a wide range of subjects, all, however, bearing on medicine. If it were possible to summarize these, we should say that they constitute a strong argument against superstition, quackery and cultism and, on the other hand, teach the value of common sense, education, and scientific medicine.

The style is pleasing, and the book is one which can be read at intervals without losing the thread of the argument.

M. P. RAVENEL

Pediatric Education. *Report of the Subcommittee on Medical Education, White House Conference on Child Health and Protection. New York: Century, 1931. 109 pp.*

This is a complete report on pediatric education by the Subcommittee on Medical Education of the White House Conference on Child Health and Protection, of which Dr. Borden S. Veeder of St. Louis is chairman. Statistical studies regarding the physician and pediatrics, undergraduate instruction, postgraduate instruction, and an outline of pediatric courses comprise the first part of the book. The second section is made up

of general discussion and conclusions based upon the statistical studies.

One is impressed at the outset with the enormous amount of work which this report entailed. It covers three main points:

1. A study of the practice of the physician in the field, and his opinion as to the adequacy or inadequacy of his medical school training in pediatrics

2. A study of the position pediatrics occupies in the medical school program, the hours allotted, subjects taught, and facilities available

3. The demands and needs of postgraduate instruction and the opportunities available

The recommendations state that:

1. Pediatrics is a fundamental basic clinical subject and should be recognized as such by medical schools. The department of pediatrics should be independent and of equal academic rank with other departments such as medicine.

2. Adequate teaching staff, hospital and clinic facilities, and laboratories should be provided and adequately financed.

3. The minimum teaching facilities should be:

Fifty beds for infants and children under the control of the head of the department

Ten bassinets for newly-born infants in a maternity hospital or division under the control of the pediatric department

An outpatient clinic with a ratio of at least 10 new pediatric admissions yearly for each student in the senior class

A well baby clinic for teaching normal feeding, growth and development

Affiliation with a hospital for "contagious" diseases

Laboratories for routine and research work

4. Pediatrics should be taught from its broad viewpoint. Particular stress should be laid upon growth and development at all ages, preventive measures, both general and specific, as well as disease in childhood, in order that the physician may be adequately fitted to meet the demands of the modern practice of medicine.

The course of undergraduate instruction should cover the following points:

The physical and mental growth and development of the infant and child and factors influencing same

The nutritional requirements of infancy and childhood including the feeding of normal infants and children

The nutritional diseases of infancy and childhood and their treatment and prevention

The "contagious" diseases: their recognition, prevention and treatment

Diseases and pathological conditions peculiar to early life

The peculiar manifestations of certain diseases in infancy and childhood

Environmental and hygienic factors which are important in early life

Social aspects of pediatrics

Certain special procedures

The importance of specific preventive measures

Certain conditions the immediate recognition of which is essential to saving life

5. Two hundred hours should be the minimum time assigned to pediatrics in the 4-year course. This will afford time for ward and clinic work in addition to standardized courses covering the subject. Electives in addition may be offered.

6. The teaching of pediatrics from a pedagogical standpoint should be carefully studied.

7. Intensive review courses (preferably of four weeks) should be continued for post-graduate students and attendance encouraged.

8. The extension courses at present given in some states should be continued, and started in states where they have not been introduced

The whole report would bear careful study by those who are interested in pediatrics, both preventive and curative.

RICHARD A. BOLT

Scientific Child Feeding in Malnutrition, Underweight, and Anorexia. *New York: Merrell-Soule Division, The Borden Company, 1931.* 48 pp. Free.

This useful pamphlet contains some 70 recipes for child feeding, in each of which the caloric value is increased by from 25 to 75 per cent by the addition of pure powdered whole milk. Full technical data as to the distribution of fat, protein, and carbohydrate, the volume, and the increase in calories are given for each recipe, so that the physician may prescribe those which are suitable for the individual child.

This plan for adding to the nutritive quality of normal recipes without affecting their bulk, flavor, appearance, or consistency, will prove of interest and value to physicians, sanitarians, and

child welfare workers who are concerned with the ubiquitous problem of malnutrition in children. JAMES A. TOBEY

Accidental Injuries. The Medico-Legal Aspects of Workmen's Compensation and Public Liability—By Henry H. Kessler, M.D., F.A.C.S. Philadelphia: Lea and Febiger, 1931. 718 pp. Price, \$10.00.

The intensively busy manufacturing State of New Jersey with its great chemical industries has provided the author a rich field for 11 years' experience as medical director of the state's rehabilitation clinic, the first one in the country, coupled with his former capacity as medical adviser of the compensation bureau.

The present work is based on an experience of more than 63,000 cases personally examined and a close following of foreign experience, especially that described by L. Imbert. It stands unique among American texts and may be expected to fill a decided want for physicians, lawyers, employers, insurance companies and industrial accident boards and commissions for guidance as conceived by an orthopedic surgeon and industrial hygienist who is constantly dealing with the medico legal features of accident and disease. The foreword is by the well known surgeon, Dr. Fred H. Albee, Chairman of the New Jersey Commission on Rehabilitation.

Seven chapters comprise an historical review, the medical aspects of workmen's compensation laws, the basis of scheduling injuries, the general pathology and end-results of trauma, and the criteria of temporary and permanent disability. The next 10 are devoted to trauma of various parts of the body with pertinent anatomico-physiological discussions and evaluations, usually in percentages, of damage and disability suffered. Chapter XVII, on Injury and Disease, deals in a masterly

fashion with this most controversial topic and is followed by a short chapter on Traumatic Neuroses. Disturbance of function is recognized as the key to compensation and attempted rehabilitation.

Hygienists will be particularly interested in Chapter XIX, which devotes 124 pages to occupational diseases, stressing the medico legal aspects of foreign and domestic legislation, with tables of schedules, matters of arbitration, the fixing of responsibility and the evaluation of disability. Some 28 pages, devoted to lead poisoning, present summaries of 213 cases in the author's series and also extensive inclusions from others, much of which is in classified and tabular form. There follow commensurate discussions of the other common industrial poisons, anthrax, radium, the dermatoses and silicosis. The final chapter is devoted to rehabilitation of the physically handicapped.

The work is essentially the author's own. He writes as one thoroughly versed in his subject and widely experienced in practice. Extensive bibliographies are appended throughout for those who would seek further. Numerous fine half-tone figures illumine the text. Tables, court decisions and case citations abound.

Health conservationists will be interested in the author's plea for a public negligence law to provide compensation for non-industrial accidents and other disabilities suffered indirectly as the result of modern congestion, speed of activity, and a chemico-mechanistic existence.

EMERY R. HAYHURST

Resistance to Infectious Diseases—
By Hans Zinsser, M.D. (4th ed.)
New York: Macmillan, 1931. 651 pp. Price, \$7.00.

This 4th edition of the standard text, *Infection and Resistance*, comes to us under a new name, owing to the fact

that the subjects treated are now recognized as being much closer to the interests of physicians occupied with infectious diseases than formerly.

During the 8 years which have passed since the publication of the 3d edition, our knowledge has broadened along many lines involving the biological characteristics, chemistry, and specificity of microorganisms and their products. The fundamental sciences have been called in to solve many problems and great advances have been made. The study of the filtrable viruses has opened an almost entirely new field, necessitating many changes in the text, which has been brought up-to-date as nearly as is possible. There has also been some change in the order of treatment, and some chapters have been practically rewritten. Disproved and outworn theories have been omitted, as well as technical details of diagnostic reactions and experimental methods.

This work has been a standard guide for some 17 years. In its present form it will doubtless retain the high place it has held in the opinion of bacteriologists and those working along the various lines of which it treats. Abundant and well selected references are placed at the bottom of the pages. A good index adds to the value of the work. The printing and make-up are excellent.

M. P. RAVENEL

International Health Year-Book, 1929 (Fifth Year). *Reports (with Vital and Public Health Statistics) on the Public Health Progress of Forty Countries and Colonies, in 1928.* Series of League of Nations Publications, III. Health, 1930, III, 8. American agent, the World Peace Foundation, 40 Mt. Vernon Street, Boston, Mass. Price, cloth, \$8.00.

This is a volume of 1,504 pages, which gives the progress in health matters in 40 countries and colonies throughout the world. It contains

many tables giving vital and health statistics. Important changes in health organization in the various countries are noted, and measures of defense against epidemics of all sorts described, including social hygiene. A section of 54 pages describes industrial hygiene in Belgium, Germany, Great Britain, Italy and The Netherlands. Short sections are devoted to the League of Red Cross Societies, the Rockefeller Foundation and the Health Organization of the League of Nations.

The section on Public Health Work in the United States deals largely with the activities of the U. S. Public Health Service, since no effort has been made to treat of the work in the various states individually.

The book is well printed and apparently accurate. It is a mine of information. The only drawback is that the data are for 1929, and give a description of the work done in 1928. Such delay is unfortunate but probably unavoidable.

M. P. RAVENEL

Biology in Human Affairs—Edited by Edward M. East. New York: McGraw-Hill, 1931. 410 pp. Price, \$3.50.

This book, according to Professor East, is offered "as a contribution toward the better understanding of the ideals, the methods, and results of biology." The term "better understanding" is significant as it presupposes that the reader will approach the material with a substantial background of scientific information. In other words the book is for the serious perusal of those with already well informed minds. In fact, the student of biology can find very stimulating reading within its covers.

Professor East begins the discussions with "Biology and Human Problems." He is followed by Frank M. Hankins with "The Prospects of the Social Sciences." These two chapters furnish a

general survey of the present aims of biology and its possible future extension into problems once considered outside of its field. The second part of the book is devoted to affairs of the mind under "The Renaissance of Psychology," by Joseph Jastrow; "Educational Psychology," by Lewis M. Terman; and "Psychology in Industry," by Walter V. Bingham. The third part takes up the body with "Heredity," by Professor East; "The Frontiers of Medicine," by Morris Fishbein; "The Outlook of Public Health Work," by Hugh S. Cumming and Arthur M. Stimson; "Physiology of Today," by E. Kennerly Marshall, Jr.; and "Zoölogy and Human Welfare," by Howard M. Parshley. The book is completed with two chapters on food—"Efforts to Increase the Food Resources," by Donald M. Jones; and "Diet and Nutrition," by E. V. McCollum.

Today, with man's environment changing so swiftly as to leave him confused in his readjustments, such a book, bringing together, as it does, authoritative, readable scientific analyses of advances in allied sciences, will be welcomed as a valuable guide to straight thinking.

LENNA L. MEANES

The Infant Welfare Movement in the Eighteenth Century—By Ernest Caulfield, M.S., M.D. New York: Hoeber. 203 pp. Price, \$2.00.

This is an interesting account of the early efforts for child welfare as carried out by a number of leaders of medical thought in the 18th century. The greater part of the book is taken up with a description of the progress of infant welfare in London. It contains an excellent review of Thomas Coram's work in establishing and continuing the Foundling Hospital in London. A chapter each is given to William Cadogan, Jonas Hanway, and George Armstrong. Many interesting sidelights on the lives of these men and their

particular contributions to infant welfare are revealed. Dr. Caulfield has given us a very readable story of the lives of those pioneers in pediatrics who were interested in the early infant welfare movement. Excellent portraits are presented of each of the men whose work is described. A list of references and convenient index of subjects and personal names complete the volume.

RICHARD A. BOLT

Berufskrankheiten. Ihre Ursache und Vorbeugung. Bibliothek für Gesundheitspflege und Arbeiterschutz der Vereinigten Staaten von Amerika—By Dr. B. Liber. Heft 4. Brooklyn: Published by the Workmen's Sick and Death Benefit Fund of the United States of America, 1930. 37 pp. Price, \$15.

This booklet contains a brief review of the occupational hazards to the health of workers, with a summary of the clinical symptoms, of the actions of the various industrial agents contributing, a list of the fields and occupations which present them, and the hygienic and sanitary measures available to the worker for their reduction or elimination.

Among the forms of industrial poisonings discussed are those by arsenic, steel, chromium, lead, and mercury. The effect of industrial dusts upon skin, eyes, digestive system, and lungs is reviewed, and there is also an analysis of the relation of tuberculosis to the various fields of industry contributory to this white plague. Silicosis plays a noticeable part in creating favorable conditions for pulmonary tuberculosis.

Diseases of the nervous system are discussed, with charges against the program of the efficiency expert and the monotony of mechanized industry as contributing to this group of functional disorders. In a secondary way these same factors contribute to the cumulative effects of fatigue upon workers and

the premature and permanent exhaustion of the worker.

One section is devoted to the symptomatology of health deficiencies and the significance in men and women of such factors as pains in different parts of the body, flat feet, constipation, exercise, and food, especially fruit, vegetables, and alcohol. A list of industrial occupations and the hazards inhering in each closes the booklet. It is of especial interest, as it emanates from the employees' side of this ever enlarging field of public health, rather than that of the investigator, physician, or scientific expert.

C. A. KOFOD

Health Stories and Practice—By William E. Burkard, Ph.D., Raymond L. Chambers, Ph.D., and Frederick W. Maroney, M.D. Illustrated by Vera Stone Norman. Chicago: Lyons and Carnahan, 1931. 256 pp. Price, \$.76.

This is a supplementary reader for third grade written to inspire pupils of this reading level to include certain fundamental health practices in their daily routine. The stories are entertaining. Some of them are based on the experiences of real as well as imaginary characters. Children still enjoy reading about fairies, gnomes and brownies. However, in this sophisticated time when they make the acquaintance of radio entertainers of their own age, they have little faith in stories about fairies who do or do not observe the health rules set down for boys and girls. The new school of health education emphasizes realism.

There seems to be an inconsistency in the general plan of the book. In the presentation of certain health habits the whys and wherefores are given, whereas this factual teaching is omitted in other stories.

The colorful illustrations add to the attractive make-up of the book.

ANNA B. TOWSE

Farm Children—By *Bird T. Baldwin, Eva Abigail Fillmore and Lora Hadley*. New York: Appleton, 1930. 337 pp. Price, \$4.00.

There are various indications that the rural child is beginning to get some of the attention he deserves: one of these indications is *Farm Children* and the research upon which it is based.

The purpose of the study was "to determine the factors that influence the physical, mental, educational and social development of farm children in certain localities." Many of us would agree, however, that in most particulars similar observations could be made, by those acute enough to do so, in the great majority of rural communities of this country.

The book starts off with a description of the physical characteristics and historical background of the two communities "Homeland" and "Cedar Creek" which were the subjects of the study. The environment, religion, recreation, and education of the farm children living in these communities are gone into thoroughly. The chapter on Social and Economic Factors in Farm Life is of especial interest in view of the discussion now rife concerning the future of the agriculturist in an industrial civilization. Very timely too is the light thrown on the controversy over the "One Room School" versus the "Consolidated School."

An appealing chapter is the one devoted to characteristics of farm children and another to activities of children in these contrasted communities. Certain detailed case histories add piquancy to the discussion. The ideals of one community apparently were those most likely to fit in with a "business civilization"; while the other community on the whole did not have its attention so firmly centered on the main chance. A chapter that should be read by all interested in rural life—or urban life either, for that matter—is the one on

Advantages and Disadvantages of Farm Life.

Most of the latter half of the book is devoted to an analysis of the physical and mental development of farm children. Detailed tables are shown of the results of physical and mental tests applied to these two communities. Some attempt is made to contrast these results with those of similar urban studies. In the physical examination tables one is rather appalled to find seven varieties of tonsils classified. The number of children included in these tests is small, precluding the possibility of drawing many precise conclusions; it is to be hoped that these data will soon be swelled by others of the same kind.

Careful and unprejudiced studies such as the one under consideration ought to be of the greatest value in giving an adequate perspective to those responsible for the spending of money for the promotion of rural hygiene. Urban experience is not a sufficient background. State and national health workers, for example, who have never had the chastening experience of work in rural communities, are apt to offer quaint panaceas for rural ills. To these in particular, and to all who are interested in rural life in general, this volume by Baldwin and his coworkers may be recommended.

MERRILL CHAMPION

My Health Habits—By *Charlotte Townsend Whitcomb, John H. Beveridge and Evelyn Estelle Townsend*. Illustrated by *Ruth Caroline Eger*. New York: Rand McNally, 1929. Book I, 149 pp.; Book II, 200 pp.; Book III, 238 pp. Prices, \$.80, \$.88, and \$.96.

These health readers follow a course of study in health education for the elementary grades, written by Miss Whitcomb and Mr. Beveridge, which has been very helpful to the teacher or director of health education planning such

a course for the curriculum. Now the authors in collaboration with Miss Townsend have prepared health stories for the first 3 grades, which present health facts in an interesting and readable style for primary pupils. The third book is the most pleasing. The animation and personification of eggs, a bottle of milk and a jar of butter is a hackneyed way of teaching health facts. Another criticism is that occasionally a story is preachy or the story children are too good and too ideal to be accepted by boys and girls with human frailties.

The appendix of health facts and the lesson plans included in Book III suggest many new ideas to the teacher. Miss Eger, who illustrated this series, has caught the spirit of the stories and her illustrations will appeal to children of the primary grades.

ANNA B. TOWSE

Health and Social Evolution—By Sir George Newman, K.C.B., M.D., Hon. D.C.L., LL.D. London: *George Allen & Unwin, Ltd. (Museum Street)*, 1930. Price 4 s. 6 d. net.

This book is made up of the Halley Stewart lectures for 1930. The Halley Stewart Trust, founded in December, 1924, has for its objects, among other things:

1. To assist in the discovery of the best means by which "the mind of Christ" may be applied to extending the Kingdom of God by the prevention and removal of human misery
2. To assist in the study of our Lord's life and teaching in their explicit and implicit application to the social relationships of man
3. To express the mind of Christ in the realization of the Kingdom of God upon earth and in a national and world-wide brotherhood

The trustees have given a wise and liberal interpretation to the will of the founder, one of the series so far having been devoted to Science and Human Progress, and the present one to the effect of health on social evolution.

Sir George Newman has few if any competitors today in his knowledge of public health and his facility in writing interestingly upon it. In these lectures he is at his best. They contain much history concerning the evolution of the public health movement in England, going back to the Middle Ages.

He quotes President Masaryk as having said, in 1918, "National humanitarianism forms the true basis of a successful practical policy," and calls our present methods "Modern Collective Humanism at Work."

He discusses in a most interesting way the gains and losses due to our present methods, and while recognizing that we are saving the lives of a number of infants (some 40,000 per year in England) who belong to a group of former contributors to the high infant mortality rate, and among whom there are almost certainly some "unfit," since the birth rate among the feckless seems to be higher than among the best stock, insists that these children shall be saved, and that England and the world in general will profit by the saving. He holds that with our present knowledge we have no means of controlling either the marriage rate or the birth rate among those considered "unfit."

We would like to quote at greater length from this delightful and informing book, but it must be read in its entirety to be appreciated. All those who are acquainted with the author will welcome his latest effort.

M. P. RAVENEL

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

St. Louis, Mo.—The 62d report of the division of health of the department of public welfare includes among its photographs a group of 2-year old children and their mothers attending the child welfare conference in one of the 12 municipal health centers. An organization chart of the health division, with several vital statistics charts, graphs, and photographs of clinic and nursing activities also add interest to this report.

Infant mortality has declined 50 per cent in 20 years to a rate of 57.2 in 1929. An adjusted general death rate of 12.8 was recorded for the year. Of the total births in 1929, 86 per cent were attended by a physician, while 54 per cent occurred in hospitals. In 1926, the division began compiling monthly statistical data concerning births and deaths by 26 health districts, and a map of these districts, with the rates, is reproduced to show the value of such compilations for administrative purposes.

The nursing personnel of the division consisted of 77 graduate nurses, 8 of whom are paid for by the St. Louis Tuberculosis and Health Society. This section has increased its scope of work through an increase in the number of clinics and conferences, which has reduced the time for home visiting somewhat, although 74,373 such visits were made last year, of which 28,386 were in behalf of tuberculosis cases, 12,862 for acute communicable diseases, and the remainder for prenatal and child welfare cases.

An increase in the volume of work carried on in the various sections of the division was accompanied by an increase in bacteriological laboratory ex-

aminations which numbered 79,903, of which 22,549 were made for practicing physicians who use this service to an increasing extent each year. There were 28,082 diphtheria cultures and 25,812 specimens for syphilis and 8,699 gonorrhea smears examined during the fiscal year.

Since the adoption of a sanitary standard for swimming pool water, associated with more frequent inspections and analyses, adopted in 1928, a marked improvement is reported in the sanitary condition of pools.

An outstanding accomplishment of the year was the enforcement of a provision of the milk ordinance requiring a physical examination and tuberculin testing of all cows from which milk is sold in the city. The policy of including in an annual report of this character recommendations for future development of health services, adopted in this report, is commendable.

Buffalo, N. Y.—Expansion of child hygiene activities during 1930 included the adoption of the child health station district plan of regularly examining groups of preschool children in different sections of the city, giving audiometer tests to school children, and extension of tuberculin tests of high school pupils with X-ray examinations of cases showing positive reactions. During the summer, 3,144 children were examined for admission to summer camps. Infant welfare clinic attendance numbered 40,961 visits, including those of 4,102 new and reopened cases. There were 301 active boarding homes for children under supervision.

Immunization procedures included 17,679 smallpox vaccinations in schools

and 2,609 by private physicians and institutions, 13,851 children with diphtheria inoculations completed in schools, and 2,221 in well baby clinics and by private physicians. Of the 16,072 children thus protected, 4,819 were under 6 years of age. Besides the physical examination of school children, 68 men and 269 women applicants for teaching were examined, while 6,647 physical examinations were given to applicants for working permits.

During 1930, a regulation was adopted by the Board of Health whereby inspection of meat animals was augmented by the designation of three places, to one of which carcasses of animals slaughtered outside the city shall be brought for examination and stamping at a specified time. Inspectors assigned to other lines of food inspection were detailed to this service, which has proved valuable. In restaurants and soda fountains, emphasis was given to the sterilization of eating and drinking utensils. Efforts of the smoke abatement division resulted in the installation of an unusual number of mechanical combustion devices.

Imperial County, Calif.—In the first annual report of the Imperial County Health Department (inaugurated as a full-time health unit July 1, 1930), one reads that for the first time in the history of the county, all pupils in the rural schools were given a complete physical examination, while diphtheria immunization was offered to all children up to 12 years of age. General death rates in the county have been lower than those for the state and U. S. Registration Area during the past 4 years, being 10.7 in 1928 and 11.6 in 1929.

In a sense, we have been pioneering in public health. We have tried to build for the future, realizing the importance of a permanent and constructive public health program to the greater Imperial County that is to come with

the completion of the Boulder Dam and the All American Canal project.

According to the U. S. Bureau of the Census, there are 30,698 native whites, 2,438 foreign born whites, 1,954 negroes, and 25,813 of other races in the county. The health department personnel consists of a medical health officer, a public health nurse, and a sanitary inspector, all full-time, with a clerk, state public health nurse, and a market milk inspector on a part-time basis.

The mimeographed report has been carefully prepared, and contains a summary letter of transmission to the Board of Supervisors from the health officer, a table of contents, a descriptive map of the county, besides interesting tables and graphs, and an historical sketch which indicates that two physicians played an important part in the development of Imperial Valley. This report contains data which "make it hard to realize that only 30 years ago a sun parched desert existed where today an inland empire rival to the Nile has become one of the most prosperous agricultural districts in the world." The county covers an area of approximately 4,200 square miles.

During the year there were 76 cases of diphtheria reported, many of a virulent type, with several cases among adults. In the rural schools, 1,575 complete immunizations with toxoid were given by the health department. Previous to these administrations, parents were advised through the mediums of the radio, the press, the weekly news letter, and talks to organizations and clubs to have their children protected by their family physician. In the city of El Centro, 475 complete immunizations were also given through the cooperation of physicians, the Chamber of Commerce and civic clubs.

It has been the aim of the health department to present to the citizens the greatest possible amount of scientific

health information in an understandable fashion. The health officer gave radio talks each Sunday night, issued a weekly health news letter to leading citizens, officials, and organizations, distributed over 500 circular letters and reports on such subjects as sanitation of school buildings, abatement of nuisances, defects among school children, plans for financing a school nursing program, and reporting of communicable disease. Newspaper articles on health subjects appeared frequently, a health department exhibit was prepared for the county fair, while hundreds of pamphlets dealing with health topics were distributed throughout the year.

Attleboro, Mass.—Reduction in deaths and lessened incidence of the common communicable diseases are noted in the 1930 health department report.

The teaching of public health becomes each year an increasingly necessary duty for health departments. . . . The most effective means of health educational work, and the only practical

way in many instances, is by means of direct communication with families in their homes. The positive results obtained by the department nurse through home visitation and the teaching of disease prevention, have made it appear advisable to employ other nurses on a part-time basis in our diphtheria prevention work. The end results of this house-to-house instruction have proved it to be of undoubted value as an educational procedure.

A chronic disease survey of the city was made by the State Department of Health. For individuals over age 40, there were, per 1,000 individuals, 2.3 with cancer in the city as compared with 4.7 in rural Attleboro. The morbidity rate for heart disease in the city was 42.6 as compared with 87.6 in the rural area; for rheumatism, the rate was 72.8 in the city as compared with 126.9 in the rural area. Other interesting data from the survey are reported.

After 8 years of effort in the prevention of diphtheria, during which time the department has given a complete series of inoculations to 3,500 children, a noticeable improvement is reported. No cases have yet occurred among the immunized children.

NEWS FROM THE FIELD

NATIONAL SAFETY CONGRESS

THE accident problem is a universal one and all persons engaged in public health work have a direct interest in promoting the development and progress of the safety movement. Special attention is called, therefore, to the Twentieth Annual Safety Congress and Exposition, which will take place during the week of October 12-16, inclusive, in Chicago. There will be 127 sessions including features and exhibits of safety equipment of particular interest at this time when health safeguards are more important than ever.

Some of the papers to be presented are: "The Evolution of Resuscitation" by Dr. Hart E. Fisher; "Industrial Hygiene in Relation to Safety" by Dr. Thomas H. Parran, New York State Health Commissioner, Fellow A. P. H. A.; "What Modern Chemistry Is Doing for Civilization" by Dr. Charles M. Stine; "A Logical Classification of Accidents" by Dr. H. B. Logie; "Cleaning in the Metal Industry" by Dr. Leonard Greenburg, Fellow A. P. H. A.

IODINE IN MILK

DR. L. J. AUERBACHER, vice president of the Dryco Milk Company, which is a subsidiary of the Borden Milk Company, is establishing an experimental factory in Newberry, S. C.

Experiments at the laboratory of the Food Research Commission of South Carolina have shown that the milk in that state, as well as the grass and vegetables, contains an unusually high amount of iodine. It is proposed to collect milk from the various sections of the state, dry it, and have the samples analyzed at the Dryco Laboratory in

Bainbridge, N. Y., as well as at the Food Research Laboratories in Charleston, S. C.

Supplies will be furnished to Dr. William Weston, Chairman of the South Carolina State Commission, for distribution to a group of hospitals in the middle west and on the Pacific coast, in which they will be used in feeding children and pregnant women, under scientific control. The hospitals have been selected on account of the ability of the pediatricians and obstetricians on duty, and also because of the high incidence of goiter in the localities in which they are situated.

The experiment is expected to extend over a period of 2 years. The object is to determine whether the children of mothers who are fed on milk containing a large amount of iodine are less liable to goiter than their forebears.

"DISEASED" BUILDINGS

IN the field of mental hygiene it has been necessary to explain to the uninitiated the difference between "mental defect" and "mental disease." But we too have been careless with our psychiatric vocabulary. Why the "Psychopathic Ho-pital"? There may be "psychopathic social workers" but state hospitals and mental hygiene clinics try as far as possible to employ safe and sane "psychiatric" social workers. Facetiously, and for the sake of brevity, professional workers have referred to students of mental deficiency as the "feeble-minded group."

"Insane" is a good old fashioned word, try as we might to discard it as a medical term, but why announce, as does a current bulletin, that the founda-

tions have been completed for two "disturbed buildings" and two "epileptic buildings" for the ——— "insane hospital"? Have you ever seen a "nervous hospital"? But even the purist is stumped at "mental institutions," the phrase has come into such general use. The technologist has given us the *televox*, the *electric man* and the robot, but it takes a psychiatrist to endow a hospital for the insane with mind.—Natl. Comm. for Mental Hygiene, New York, N. Y. *News Release*.

PERSONALS

I. RUSSELL RIKER, Member A. P. H. A., formerly Senior Sanitary Engineer of the New Jersey State Department of Health, recently resigned after 16 years' service and is now connected with the Borough of Princeton, N. J., as personal representative and Resident Engineer on their new sewage project consisting of 13 miles of trunk sewer and a new two million gallons sewage treatment plant.

DR. CHARLES J. SCAVARDA has been appointed Health Officer of Flint, Mich.

CLIFFORD CHARLOCK, F.A.P.H.A., after 36 years' service as Health Officer of the Island of Hawaii, retired on June 30. The Board of Health at its meeting on June 17 passed a resolution reading in part as follows:

BE IT RESOLVED: That the Board of Health does hereby express its recognition and appreciation of Clifford Charlock's loyal service to this Board and the community, and does extend to him its wishes for many years of happiness and contentment upon his retirement.

JOSEPH S. CACERAS, Member A. P. H. A., succeeds Mr. Charlock.

JOSEPH P. KANE, M.D., has recently accepted a position as Director of

County Health Work with the New Mexico Bureau of Public Health. Through special funds provided by the Commonwealth Fund organizing county health work in that state, this is being undertaken. Dr. Kane has had experience as a full-time health officer both in urban and rural districts. For some time Dr. Kane was associated with the Gorgas Memorial Institute and for the past two years was a member of the field staff of the Committee on Administrative Practice of the American Public Health Association, serving as Health Consultant for the Inter-Chamber Health Conservation Contest.

JACOB C. GEIGER, M.D., has been appointed by Mayor Rossi as Health Officer for the City and County of San Francisco, Calif., to succeed the late Dr. William C. Hassler.

CONFERENCES

October 5-9, Ohio Welfare Conference. Akron, O.

October 12-16, Twentieth Annual Safety Congress, Chicago, Ill.

October 16-17, Fall Meeting, New York State Sewage Works Association, Ithaca, N. Y.

October 19, 20, Conference of the Child Study Association, New York, N. Y.

October 19-21, Fourteenth Annual Meeting, The American Dietetic Association, Cincinnati, O.

October 22, 23, Seventh Annual Meeting of the Missouri Water and Sewerage Conference, Jefferson City, Mo.

November 9-14, the Ninth Texas Sanitarians' Short School, Houston, Tex.

July, 1932, The Second International Conference of Social Work, Frankfurt, Germany.

September 6-9, 1932, Annual Meeting of the International Union Against Tuberculosis, The Hague, Holland.

Presidential Address*

HUGH S. CUMMING, M. D., F. A. P. H. A.

Surgeon General, U. S. Public Health Service, Washington, D. C.

ON behalf of my fellow members of the American Public Health Association it gives me pleasure to express our very sincere appreciation of the opportunity which has been given us to meet in this city which nature and man have combined to make beautiful—a city which, for every educated person, has written upon each page of its history, covering nearly 300 years, romance and tragedy, as well as glorious achievements, both by the early French settlers and their religious leaders and by the British who followed.

We are particularly appreciative of the honor of having your welcome extended by such distinguished representatives of the Dominion, Province, Municipality, and Church.

Those of us who belong to medicine and its allied branches, and whose life work is devoted to preventive and curative medicine, feel that perhaps we have some claim upon your great country and her hospitality; for while this city began as a religious colony when Maisonneuve and his little band of religious enthusiasts landed here May 18, 1642, and while the wilderness was conquered by priests and soldiers and statesmen, we like to recall that the first man to bring out his family and make his home in Canada was the apothecary Hebert, and that the first man to found a seigniory and settle it with inhabitants was Dr. Robert Giffard, Seigneur of Beauport. Nor do we like to forget that it was to this same Dr. Giffard that King Louis XIV gave the first patent of nobility granted an inhabitant of Canada.

It is pleasant, too, for us to know that in your later years a country doctor became Premier of Nova Scotia, your High Commissioner in London, and finally Prime Minister of Canada.

* Delivered before the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 14, 1931.

We feel that with such an history and tradition it is little wonder that you have builded such magnificent medical schools, laboratories, and hospitals with a splendid succession of clinicians and research workers from whose ranks we of the United States have so freely drawn and to whom the world owes much.

May I not add that, as Chief of the U. S. Public Health Service, and personally, I do not feel the need of any formal invitation to come into the territory of my friend, your Deputy Minister of Health, Colonel Amyot, who for years in the laboratory, later on the field of battle, and in the field of preventive medicine, has won the respect and affection of all of his colleagues, both on this continent and abroad. I am sure he has the same sentiments toward us. We accept reciprocally and without reservation the statements made and the procedure adopted by each other in international matters under our respective jurisdictions, and feel free to call upon each other for aid in times of stress and trial; while in international bodies we have nearly always voted together.

Throughout the ages it has been the custom of religious bodies to impose upon themselves various kinds of self punishment for the good of their souls and for after recompense, reward, and relaxation. Following their example this Association, in common with other similar scientific bodies, has imposed upon such of its members as are present the penance of listening to its President for the time being report upon the state of health of America, and upon its internal affairs. From year to year my predecessors have in pessimistic tones "viewed with alarm," or with triumphant voices have "pointed with pride." You are about to have this penance inflicted upon you.

Our Association, in common with all of the social clubs, voluntary and scientific organizations with which I am familiar, has suffered both in membership and in the collection of dues as the result of the worldwide economic depression. This Association has not suffered more than others and I see no reason for undue pessimism.

You are familiar with the fact that our Secretary, Mr. Calver, after a number of years of devoted service, resigned last spring. I am sure you all will join me in wishing him success.

I deem it one of the most fortunate events in the history of the Association that the Executive Board succeeded in persuading Dr. Kendall Emerson to become our Executive Secretary; for he has brought to us a wide experience here and abroad, a seasoned, sound judgment, a rare personality and wide acquaintanceship which it would be difficult to duplicate. I hope that he may be persuaded to remain.

I am sure that all of you who have an opportunity to read the

JOURNAL of the Association will agree with me that it has never been so well edited or contained such interesting and constructive material as during the past year, and that you will join with me in an appreciation of the work which has been done by the editor, Dr. Ravenel, and his coworkers.

The Association has suffered during the past few weeks an almost irreparable loss in the death of our President-Elect, Dr. William C. Hassler, Health Officer of San Francisco, and Dr. Lee K. Frankel, one of our former presidents.

I have known Dr. Hassler for 30 years; he was a man of the highest personal integrity and honor, a man of strong convictions and unswerving loyalty to his friends and ideals, and a loyal and devoted member of the Association. When I was asked several years ago to nominate a municipal health officer for a League of Nations Interchange in Europe I unhesitatingly suggested Dr. Hassler.

Lee K. Frankel we all knew and loved. Devoted to the betterment of his fellow man, he brought into his work a catholicity of interests, a splendid intellect and judgment, combined with a gentle nature which endeared him to all with whom he came into contact. Providence placed him where he had large opportunities for good, and he employed them to the utmost. Few men have done more for the health and happiness of their fellow men.

I suggest that we all stand for a moment with the prayer that their lives may serve to stimulate those of us who carry on their work.

Within the memory of many of us our race has passed through an epoch-making period unequaled in the annals of history; in its beginning little more was known of the etiology and epidemiology of disease than in the period of Hippocrates; synthetic chemistry was unborn; in applied physics the electric light and telephone were curiosities; in transportation the first electric tram was used; in sociology there was but the first awakening of the public consciousness of the duty and necessity of community effort and of the close interdependence of the different classes of society.

It is unnecessary for me to attempt to recall to such an audience the developments, the changes, the discoveries, during this period; we have eaten largely of the fruit of the tree of knowledge.

And into this great period came the World War and its immediate aftermath, the destruction of old landmarks in politics, in faith, apparently in all things that were.

The fever of war was apparently diverted into other fields of activity. The war itself had brought about the recognition of the necessity for group action in production, transportation, and health, no less

than in military movements; and indeed for the first time there was a consciousness of the dependence of military success upon concerted action by the civil population. Large sums of money and large powers were given for the purpose of improving the health and welfare of non-combatants. Not infrequently these powers and resources were placed in the hands of inexperienced but ardent patriots who for one reason or other were not in the military forces of the country and who were not familiar with the traditions, laws, and the orderly procedure of our forms of government.

It is perhaps significant, too, in this respect that it was during such an unsettled period that we had in the United States national woman suffrage for the first time, and that in all of the allied countries women were first brought into public life and political power.

Largely as a result of this increased consciousness of the importance of the public health movement having been awakened in the mass of our population, there has been a constantly broadening interest in the whole field. Not only has this been true among those elements interested chiefly in the humanitarian side, but, perhaps more important, industry and finance have been made aware of the vital significance of mental and physical well-being, not only to the individual, but to themselves and to government. Leaders in industry and finance have had brought to them the enormous dividends from true research by competent personnel.

During this same period our countries have had an unprecedented era of prosperity for the masses and the accumulation of great fortunes by individuals and corporations.

As a result of popular interest and demand on the one hand, local, state, and national health organizations have had their fields of activity broadened and their resources increased, while individuals have given enormous sums of money for the enlargement of existing, and the creation of new endowments and funds for the promotion of health and welfare, not only in the United States but throughout the world.

Able and willing to pay larger salaries and affording greater opportunities for usefulness than most governmental agencies, and with the wise advice of great men, an inestimable good has been done by many such endowments and nonofficial agencies, not only directly in the work they have done in field, laboratory, and schools, but perhaps even more in their education of the people and stimulation of governmental activities; for in any representative form of government, official action follows public sentiment and urge. The improvement in health conditions owes much not only to such members of the medical and allied professions, but to the non-medical socially minded men and women who have led such movements.

Unfortunately, however, the ease with which fortunes have been accumulated during this period has resulted in some instances in exemplification of the old adage, "Easy come, easy go." Many of us in a position to observe have been astonished at the ease with which often honest but incapable enthusiasts have secured large sums of money which have been dissipated in unwise and ill-directed research or investigations, and out of which has arisen a mushroom-like crop of so-called experts in various lines of health and welfare endeavor. We have had several examples of this during the past year. It is scarcely necessary to invite the attention of both medical and allied professions to the danger of such movements.

There is another problem which I feel it my duty to bring to your attention. I do this with some hesitation, because it is apparently a reflection upon scientific men as a body. Few men and women in medical and allied public health professions perhaps realize the effect of the rapid advances which are being made in industry, particularly in chemistry, upon the inter-relationship between industry, public health, and the public whom they serve. On the one hand large corporations are maintaining at great expense research workers and laboratories not only for purposes of advancing their interests by scientific research but for necessary defense purposes, just as their legal departments are maintained. On the other hand, our educational institutions, as well as individuals, have research laboratories, in most of which earnest work is being done in scientific spirit for the betterment of their clients and the public. Unfortunately, however, not all of the individuals who labor in the realms of science are perfect, and from time to time there is being brought to the attention of those of us in public office apparent attempts to threaten corporations which would seem to border very closely upon the high-jacking and blackmailing of other classes.

It seems to me to be a peculiar duty of this Association to exercise such influence upon its members as may best cause the retention by them of a true scientific attitude, whether it be after accepting an honorarium or in the course of governmental work. There is perhaps in this field of professional endeavor as nowhere else necessity for calm judgment, ability to recognize a balance of values, and intellectual honesty which after all is the most important attribute of a true scientist.

I venture to say that our Association itself should be particularly careful to observe that injunction of the Apostle, "Avoid the appearance of evil."

There is another condition in connection with the present state of

research, curative and preventive medicine which is well worth the serious concern of this Association and which has recently attracted the attention of our sister organization, the American Medical Association. The applications of the results of research in physics and chemistry to medicine are now rapidly made known to the public at large through the medium of the press, radio, and the moving picture.

Medicine, health, and hygiene are popular subjects for exploitation by both the trained and untrained. Advantage is being taken by certain commercial interests of this general interest in and superficial knowledge of such matters as the use of the different wave lengths of the spectrum, and of the existence in foods of the so-called vitamin group, until their extravagant and unwarranted claims in some instances result in danger to the public through their use by unskilled persons, and on the other hand in waste of the public's money for the purchase of articles and foods which have no particular value as curative agents. This constitutes a problem not only because of the financial aspect of the matter, but because it inevitably will result in disappointment, disillusionment, and contempt for real achievement in science.

That there has been a greater advance in both curative and preventive medicine during the past few decades than in any previous era is demonstrated by the results, as shown by lessened mortality and morbidity rates, as well as by the public interest, to which allusion has already been made, as manifested both by voluntary organizations and by largely increased appropriations by municipal, state, and federal governments. It is not necessarily disparaging to say that much of this effort and large sums of money have perhaps been dissipated in our progress. Medicine and sanitation are not alone in not having arrived at perfection. This is perhaps not the time or place to compare our efficiency with that of other lines of individual and governmental effort.

There is, it seems to me, at least in the United States, a most serious problem upon the solution of which we should concentrate our efforts during the coming years. That the United States is not unique in this respect is shown by the following quotation from that extremely interesting book, "Four Centuries of Medicine in Canada":

Public health in Canada is not yet freed from the politician who overrides the recommendations of the fully qualified public health official, makes appointments, as he sees fit, that destroy the morale of the entire working system of the department and indefinitely retard progress; nor is it freed from the untrained, unqualified official who to win recommendation will stoop to plunder.

I allude to the unsatisfactory condition which exists through almost all of our country in respect of the personnel in public health

work, especially regarding methods of selection, tenure of office, and compensation. Until recent years the only school for public officials was the school of experience, a rule of trial and error; and we know many leaders now living, and recall others dead, who have blazed the way for those of us who are still carrying on. But we must remember that public health work only a few years ago consisted chiefly of suppressing epidemic diseases, improving environmental conditions and safeguarding milk and water supplies; and such men grew along with our broadening conceptions and knowledge.

As a result of recent discoveries in the sciences and their application to public health, and no less as a consequence of the realization of the truths of the interdependence of individuals, and even of nations—that “no man liveth unto himself and no man dieth to himself,” that the strength of a people depends upon the moral, mental and physical health of its individuals—there has come a realization that the public health is influenced by environment, heredity, industry, economics, morality, education. The insanitary dwelling, the malarial stream, the syphilitic or idiot parent, the hazards of dusts or poisons, the living wage, temperate life, knowledge of diseases and how to avoid them, all come within the sphere of the present public health movement.

Nor is there justification for that artificial division of medical science into preventive and curative medicine. We are all members of the same body whose object is to prevent illness and pain and premature death. The interests of the people, as represented by government, are equally affected by helpless individuals, whether made so by heart disease, rheumatism, or paresis, as by smallpox or plague or poliomyelitis.

The research worker in the laboratory or in the field of epidemiology and the surgeon or physician at the bedside are all directly or indirectly, consciously or unconsciously, public servants working for the public good.

The ideal for which we aim is the application of every available means for the prevention of disease or injury and the provision of suitable treatment for all sick or injured. The problem is how this ideal may be attained with the greatest good to the common weal.

The solution is not to be found by mathematical formulas nor endemic nor ecumenical council; it will differ in some phases in different countries, states, or provinces, indeed in each community.

Neither bench nor bar, pulpit nor national military defense, needs men of greater professional training, of sounder judgment and courage than are required for the solution of these problems.

Public health is a specialty; but just as one who knows only op-

erative surgery is a poor surgeon, so should the efficient health officer have an intimate knowledge of the whole field of medicine. There is no longer any dearth of facilities and opportunities for the education and training of suitable men who choose as their life work leadership and general staff work in the field of public health; not only have individuals and foundations built magnificent schools of public health manned with able faculties, but there are opportunities in the federal and in some of the state and provincial services and laboratories for such training. Even more important in a broader sense is the commendable action which is being taken in some of our best medical schools to teach the preventive medicine and public health import of practising medicine to all medical students.

We may no longer consider as a complete or efficient state or local health organization a small group of salaried officials who confine themselves to the suppression of epidemics, the collection of vital statistics, and the enforcement of ordinances. These are necessary for staff and intelligence, for research in field and laboratory, but it is also necessary that the local state or provincial medical associations shall be brought into close relationship, that there shall be a mutual understanding with them and with voluntary agencies so that all may work together toward the common end. You will pardon me if I mention Detroit as one example of what may be done.

But to reach this goal there must be competent leadership. There have been in the past, and are now, many great leaders in the field of preventive medicine, pioneers, men of initiative, men with broad, almost prophetic vision; but I am sure that you will agree with me that there is room for much improvement, that the general average of health officers, particularly in the local field, leaves much to be desired, and that, consequently, there has been an unnecessary waste both of effort and money to accomplish the results which have already been attained and which makes much more difficult future progress.

During the past decade or so in the world of industry and finance, both in our countries and abroad, there has been occurring reckless advance in all lines of human endeavor without due thought for possible days of adversity and need. This has been true in public health and welfare as well as in other fields. We have reached the stage now where it is not only desirable and wise, but necessary, that we should not remain passive in a state of pessimism and despair but in a truly scientific spirit should carefully study the mistakes which have been made in the past and survey our course for the future. This is no less necessary for this Association than for governmental and non-governmental agencies, and I commend to your careful consideration a study

of the budgetary possibilities of the Association with a view to governing our activities accordingly.

The people of our European and American regions came out of the World War feeling that the old order had changed and all things were new in the social and political world; nations and individuals were torn from their moorings, swept away from their courses. Scientists and sociologists entered into a decade unparalleled in its feverish activity. The veil of mystery was torn from many secrets of chemistry and physics, and the habits and very thoughts of people were changed. History and experience were considered with contempt, and warnings of the thoughtful were but voices crying in a wilderness.

Knowledge came, and with it apparently universal wealth and prosperity; but wisdom lingered.

It is not necessary for me to tell you that this old world is a very sick patient now; following the period of maniac excitement there is a physical, mental, and moral depression. Around her are many would-be physicians, with nearly as many diagnoses and prognoses. Many are mistaking symptoms for causes, and are suggesting empirical or quack remedies; others are nihilistic in their therapy and pessimistic in their prognosis; while, thank God, there are others earnestly trying to find the true causes and their remedies.

It may well be that future generations will smilingly refer to this period as a beneficial purge given us in the Dispensation of Providence.

Meantime, may I not appeal to you of the medical and allied professions, trained as you are to contact the realities, to "sit steady in the boat" and, avoiding panic and pessimism, assist those whom we have in authority in our respective governments to resist the urge to give either stimulants or narcotics or remedies which, while they may give temporary relief, may cause irremediable injury to our countries and retard their convalescence.

I am particularly glad on this occasion, both on behalf of the Association and personally, to welcome our colleagues, Sir Allan Powell, Drs. Buchan, Porter, and Fenton, who have come to us from the Association of Medical Officers of Health of Great Britain. I am sure that they have brought with them some of the wisdom and experience of that great Mother Country to whom we have looked in the past for leadership and inspiration in matters of public health.

Drought and Health*

MAZŸCK P. RAVENEL, M. D., F. A. P. H. A.

University of Missouri, Columbia, Mo.

HISTORY abounds in instances of diseases following shortage of food, which may range from slight deficiency to absolute starvation. The Old Testament recounts many instances in which famine was sent upon the land resulting in pestilence and death. According to the belief at that time, these occurrences were due to the anger of God over the disobedience of his commands by his people, or the worship of false gods by other peoples.

And I called for a drought upon the land, and upon the mountains, and upon the corn, and upon the new wine, and upon the oil, and upon that which the ground bringeth forth, and upon men, and upon cattle, and upon all the labor of the hands.¹

A typical story is that of Elijah and Ahab. After some 3 years of drought and famine, Elijah entered into a contest with the prophets of Baal over calling fire down from heaven to consume a sacrifice. He won, and after slaying the prophets of Baal by the brook Kishon, Elijah said to Ahab:

Get thee up, eat and drink; for there is a sound of abundance of rain. . . . And it came to pass in the mean while, that the heaven was black with clouds and wind, and there was a great rain.²

While modern science makes us reject the etiology accepted by the Old Testament peoples, these stories are interesting in showing the correctness of their observations and the recording of the facts.

There is no doubt that when there is lack of food on a large scale, such as may affect a community or a people, pestilence is sure to follow; and there is a widespread belief that famine is a direct cause of pestilence.

The lack of food, either as regards quantity or quality, certainly lowers resistance to certain infections, though not to all. The direct effect of starvation is a lack of vitality and increased susceptibility to disease. During times of food shortage an indirect effect is always seen in a lack of hygienic measures and cleanliness, an increase in

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

vermin, and the presence of other factors which favor the spread of certain diseases, especially typhus fever, plague, relapsing fever, and others of similar character.

During the World War we had a striking example of the effects of lack of food, which was deficient not only in quantity but also in quality, in the so-called war edema seen among the people of the Central Powers. This was clearly the result of underfeeding on a ration which was low in protein and deficient in fat. It was followed by displacements of the internal organs due to the loss of the supporting fat, and deficiency diseases such as rickets. The incidence of tuberculosis was increased and infectious diseases became more prevalent.

The most common cause of lack of food is failure of crops, which is usually more or less local. Where the means of transportation are lacking, or are destroyed, as during the great flood in the Mississippi Valley, starvation may occur though abundance of food is near at hand.

In 1921-1922, while some 25 million people were starving in the Volga region and several million died, there was a great surplus of food in America, Australia, Argentina, and even in parts of Russia. In 1930, while millions were starving in China, wheat was a drug on the market in practically all other countries.

While this discussion, as far as the public health aspects go, centers on the problems of drought, the Mississippi flood must be remembered, as the drought conditions now existing have been unquestionably aggravated by the destruction which took place during that disaster.

According to the U. S. Public Health Service, 22 states are included in the drought stricken area of this country, most of these being in the middle, south, and southwest.

Conditions became so bad that in February, 1931, Congress appropriated \$2,000,000 to our Public Health Service for medical aid in these states. This was a strictly emergency measure, and the appropriation will cease to be available on June 30, 1932. It is perhaps needless to say that most of this money will be expended in the rural areas, the inhabitants of which have lost not only their staple food crops, but also their vegetable and garden crops. The rôle played by vitamins in nutrition emphasizes the seriousness of this latter item.

The engineering features of the situation are amply provided for in the reports which are to follow. It need only be said that throughout extensive areas not only have the crops been lost but there has also been a great shortage of water for household purposes and for cattle. The direct result has been that water has been hauled from unprotected streams and springs, wherever such sources were available, for drinking and to fill cisterns.

It is perhaps too early to form a definite opinion as to the effect of this measure as other factors have been concerned, the relative value of which we are unable to determine at present. In general it may be said that there has been an increase in the prevalence of intestinal troubles, particularly diarrhea and enteritis in children under 2 years of age. Other papers will give the details of the outbreaks of intestinal trouble observed in some of the eastern states, especially at Charleston, W. Va., and cities located along the Ohio Valley.

In Arkansas, Dr. Garrison, the Health Officer, reports the amount of malnutrition among rural children for 1930 is double that for 1929. The disturbed conditions relating to private, and in some cases public, water supplies were counteracted by intensive precautionary measures.

In that part of Missouri south of the Missouri River many cases of malnutrition have been observed, intestinal disorders have been common, and typhoid fever has increased markedly, as shown in the following figures:

Total for years 1929 and 1930:

1929—614 cases reported

1930—793 cases reported

Indicates an increase of 29 per cent.

Total for state last 6 months of 1929 and 1930:

Last 6 months 1929—341 cases reported

Last 6 months 1930—647 cases reported

Indicates an increase of 90 per cent.

Total for 55 drought counties 6 months of 1929 and 1930:

Last 6 months 1929—156 cases reported from 55 drought counties

Last 6 months 1930—352 cases reported from 55 drought counties

Indicates an increase of 125 per cent.

Total for 59 non-drought counties 6 months of 1929 and 1930:

Last 6 months 1929—185 cases reported from 59 non-drought counties

Last 6 months 1930—295 cases reported from 59 non-drought counties

Indicates an increase of 59.5 per cent.

The conditions in regard to typhoid fever are not quite so bad as the data seem to indicate, as the great increase was due largely to an epidemic in one county in which local factors seem to have played a part.

Reports from the directors of the units established for the drought emergency show a comparatively high incidence of malnutrition, as evidenced by underweight, and many cases of rickets have been observed, though it must be remembered that data for other years are not available.

In Tennessee there was a slight increase in typhoid fever, from 1,575 cases and 307 deaths in 1929 to 1,732 cases with 324 deaths in 1930, the rates being 11.8 and 12.4 for the 2 years respectively. The death rate from diarrhea and enteritis under 2 years of age increased from 23.8 in 1929 to 28.2 in 1930.

A bright spot in the returns is that there has been a decrease of almost 50 per cent in the cases and 20 per cent in deaths from malarial fever. It seems fair to believe that some of this decrease, at least, is due to drought conditions, although Tennessee has for some years past been carrying out an intensive anti-malarial campaign including the screening of houses.

In Kentucky, A. T. McCormack, M.D., State Health Officer, reports 100 more deaths from typhoid fever than in 1929, almost all of which occurred in counties without health organizations, and where little or no immunization was done. The death rate among children under 2 years from diarrheal diseases has been considerably increased, while outbreaks of diarrhea and dysentery have been reported.

In the counties with health organizations, there was good coöperation on the part of the people, and a large part of the drinking water was boiled. Nearly 1 million persons were immunized against typhoid fever.

The incidence of pellagra has increased, though exact figures are not available.

In Oklahoma, the crop failure caused defalcation in taxes, which was responsible for the breaking down of county health service, while scarcity of food led to migration to larger centers of population, and especially to the oil fields. This increased the problems of the health departments.

The most marked effects were noted during the last 6 months of 1930 and the first 3 months of 1931. The incidence of typhoid fever was slightly greater in 1930 as compared to 1929, but decreased for 1931. Extensive educational and immunization campaigns were carried out.

Dysentery followed the same general course, some increase in 1930 and a marked decrease for 1931. Pellagra has shown a great and steady increase, 219 cases for 1929, 298 for 1930, and 441 for 1931. These figures are for 6 months of each year only, in order to make them fairly comparable with 1931. Reports from the psychiatric hospitals indicate an increase of nearly 20 per cent in the number of admissions of pellagrins for 1930 over 1929.

It is manifest that this paper gives an incomplete account of what has happened. The ultimate effects of the drought will not be known

until very much more complete studies have been made and a longer time has elapsed. Except for the intestinal outbreaks studied by Dr. Veldee, the general effects of the drought on health are those which have been recorded for ages in the literature. We will unquestionably derive beneficial effects through an arousing of general interest, the stimulation of health officers and public health workers, and the recognition of the disaster by Congress. Undoubtedly the final effect will be precautions to forestall similar disastrous results in the future.

How Old Is the Word "Antiseptic"?

WHILE the words "antiseptic" and "asepsis" seem to be modern expressions, we find "antiseptic" in medical literature in the middle of the 18th century. It was also commonly used by the laymen and we find the following good advice in the publication, *Gentleman's Magazine* (1751): "Myrrh is twelve times more antiseptic than sea salt." Moreover I note the word antiseptic defined in St. Blancard's lexicon (1777) as follows: "Antiseptica, sunt remedia interna et externa, quae putridini resistunt."

There is a very interesting letter by George Foster, October 13, 1791 (Herrig's Archiv. Bd. 93. S. 41), wherein he describes treatment during an illness, "I had no desire to eat, etc., all the symptoms of a general breakdown. Drank quantities of vitrol acid and ate kraut conserve. In short, I was kept antiseptic and after a few days I became better. I now felt hollow and empty and very weak on my legs."

The kraut conserve was believed to be antiscorbutic. Chlorine and its combinations, sodium chloride and chloride of lime, were known as strong antiseptics through Semmelweis, especially in Wien and Budapest. Iodine later first became pushed to the foreground.

In Lister's time a number of antiseptics were used, for instance, alcohol and glycerine.

The surgeons of that time almost without exception used antiseptics with the idea of making decomposition harmless. Semmelweis, who used antiseptics on the hands, the main carrier of infection, to prevent infection, was one exception. "You should work with clean hands!" said Semmelweis, while Fleetwood Churchill said, "A gentleman's hands are clean" (E. Ebstein, The use of gloves in obstetrics in the year 1758. *Monatschr. f. Geburtsh. u. Gynäk.*, 79: 39, 1927).

Lister's teachings found little sympathy in England. They explained that the Germans are known as dirty people, therefore antiseptics might be necessary there, but in England they are superfluous.

It was not necessary in England to demand the cleaning and disinfection of the finger nails because a gentleman cleans his finger nails in his sleeping room.—Dr. Erick Ebstein, Leipzig, *München. med. Wchnschr.*, 76: 2168, 1929.

The 1930-1931 Drought and Its Effect Upon Public Water Supply*

E. S. TISDALE

*Director, Division of Sanitary Engineering, West Virginia State Department
of Health, Charleston, W. Va.*

THE 1930 drought has dramatized as never before the need of safe, adequate, palatable, public water supplies. The widespread interest of the general public in the drought, the suffering it caused, the financial loss to those living in farming and rural areas, the anxiety of water works men and those in industries dependent upon water, all have been factors making for more adequate water supplies and for more completely equipped and better operated water filtration plants.

This drought and the disastrous flood over the Mississippi watershed in 1927 have acted so to accentuate public health work in the mind of the everyday person that public health machinery in all the states lying within the zone of these catastrophes is now far more efficient than it was 5 years ago.

Each state sanitary engineer in the sorely distressed states has summed up the conditions which have existed in 1930 and to April, 1931, and it is from these supervisors of public water supply and sanitation who are constantly in touch with such conditions all over their states that the material in this brief summary has been obtained. In each of the affected states, the Division of Sanitary Engineering of the State Health Department was able to lend immediate help when water supply emergencies arose in the cities over their state.

The gigantic size of the problem is difficult to realize but some definite conception can be gained by picturing the states of Maryland, Pennsylvania, Ohio, West Virginia, Virginia, and Kentucky which embrace a territory of 200,000 square miles, and imagining water standing 2 feet deep over this entire territory. That is the amount of water which these 6 states did not get in 1930 and hence was not available for vegetation, streams, ground water supplies, and the manifold other water uses. Is it any wonder that emergencies were created such as were never known before?

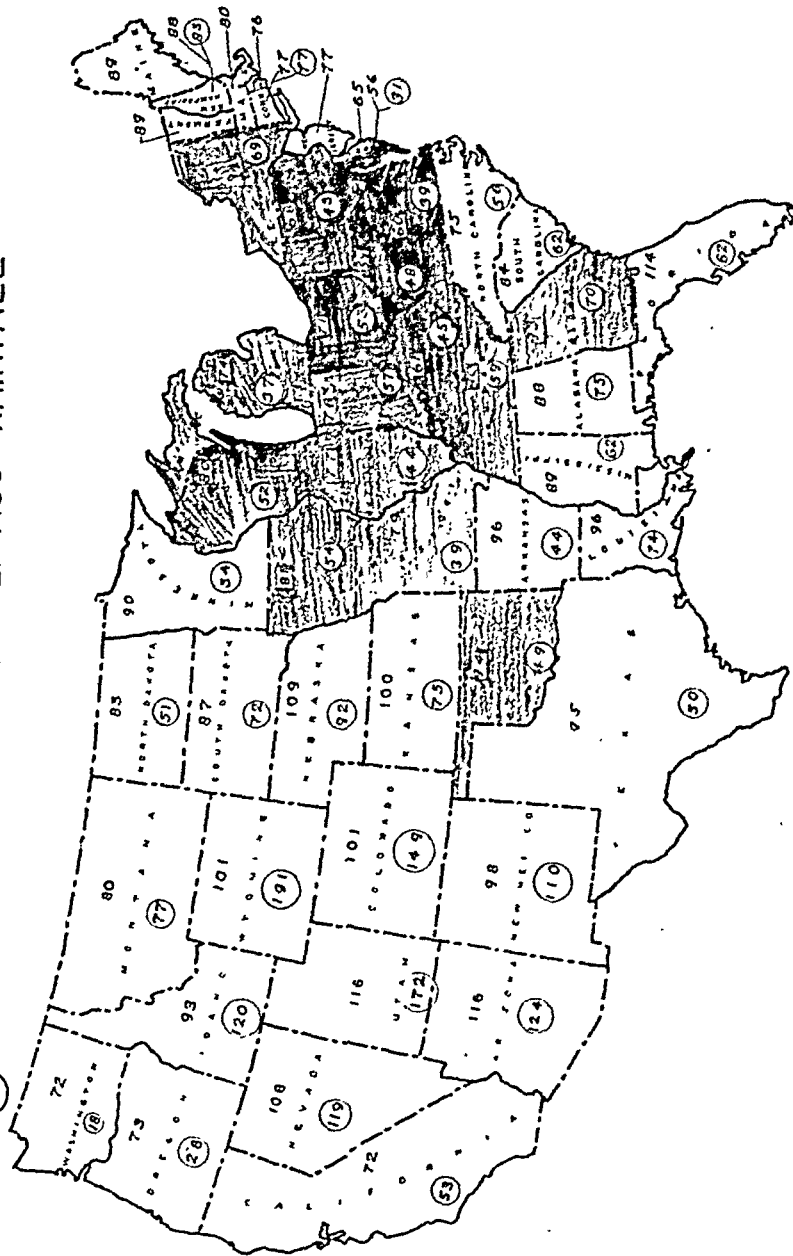

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

These 6 states—Maryland, Virginia, Pennsylvania, West Virginia, Ohio and Kentucky—according to Prof. Floyd Nagler of Iowa, who summarized the drought situation in Iowa before the Iowa Water Works Conference in 1931, had approximately 60 per cent only of the normal annual rainfall and they constituted the heart of the drought area where most severe conditions obtained.

Prof. Nagler prepared maps showing the percentages of normal precipitation for July and August, 1930, in some cases to run in the zone of 30 per cent and 40 per cent of normal. He emphasizes the

1930 DROUGHT

83 PERCENT OF NORMAL ANNUAL RAINFALL
 70 PERCENT OF NORMAL JULY-AUG RAINFALL

fact that the excessive evaporation rate produced by the high summer temperatures with extremely low rainfall was an additional factor in causing the unprecedented depletion of stored water supplies and the unusual depletion of shallow ground water supplies from which evaporation takes place by capillary action and transpiration.

Every state which has analyzed the present drought situation is now commenting upon the deficient ground water supply and the possibilities of trouble arising in the fall of 1931 from this shortage.

The drought experiences of these 6 states have been outlined at some length in the various state water works meetings and before the American Water Works Association convention at Pittsburgh in May. However, it may be of interest to look at the problem from the standpoint of the entire area, considering the different types of problems which arose, how they were met, what new angles of water supply have been stimulated, and note the aggregate effect of the whole on public health.

Before considering the drainage basins of the Ohio and Potomac Rivers where lay the heart of the drought, we shall look for a minute at the fringe of states surrounding these, where drought conditions had to be met also.

CONDITIONS IN FRINGE OF MAIN DROUGHT AREA FOR 1930 AND FOR JULY-AUGUST

New York—Percentage of normal annual rainfall, 82; July-August, 69. Holmquist reports 65 public water supplies seriously affected by the drought, and several cities taking action to obtain permanent, enlarged water supplies. Rural supplies of thousands of farmers failed and they had to take their stock miles for water. Three hundred and seventy-eight water works managements were warned of a possible drought in 1931 on account of the sorely depleted ground water.

Illinois—Percentage of normal annual rainfall, 77; July-August, 44. Ferguson had 15 communities affected where emergency measures were adopted. So eager were farmers for rain that even the first run-off from roofs laden with dust was directed into the cisterns.

Michigan—Percentage of normal annual rainfall, 74; July-August, 37. Rich reports no real suffering, but the ground water levels were lowered.

Wisconsin—Percentage of normal annual rainfall, 82; July-August, 52. Warwick states that streams and lakes were low with luxuriant algal growths, causing widespread tastes and odors.

Indiana—Percentage of normal annual rainfall, 76; July-August, 57. Finch says that the state experienced troubles but escaped alarming water supply deficiencies.

Iowa—Percentage of normal annual rainfall, 81; July-August, 54. Wieters advises that Iowa had many cities seriously embarrassed, but no complete failures—ground waters down to low ebb in some cases.

Missouri—Percentage of normal annual rainfall, 79; July-August, 39. John-

son advises that many supplies were so depleted that supplementary sources were drawn upon. Few cities were actually short of water.

Oklahoma—Percentage of normal annual rainfall, 94; July–August, 49. Darcey claims that no municipal supplies failed completely. However, taste and odor troubles in surface water supplies were so intense that citizens would not use the public supplies. Old wells, springs, and cisterns were resorted to, resulting in a great increase in the number of dysentery cases throughout the state. Twelve cities have adopted ammonia-chlorine control of taste since January, 1931.

Tennessee—Percentage of normal annual rainfall, 80; July–August, 59. Morton reports considerable trouble occasioned in some 13 cities and towns when springs and wells failed. Uses of water were restricted and the chlorination of emergency water supplies practised.

Georgia—Percentage of normal annual rainfall, 93; July–August, 70. Clarkson states that 8 cities found it necessary to develop emergency water supplies. Much permanent improvement has been obtained in construction and operation of water purification plants.

THE HEART OF THE DROUGHT AREA

The heart of the drought area of 1930–1931, where the outstanding difficulties with respect to public water supplies were encountered, lay on the watersheds of the Ohio and Potomac Rivers for the most part. The percentages of normal rainfall in 1930 were:

RAINFALL JULY–AUGUST, 1930

	Percentage of Normal	
Pennsylvania	Annual	68
	Jul.–Aug.	43
Maryland	Annual	56
	Jul.–Aug.	31
West Virginia	Annual	59
	Jul.–Aug.	48
Ohio	Annual	71
	Jul.–Aug.	53
Virginia	Annual	60
	Jul.–Aug.	39
Kentucky	Annual	61
	Jul.–Aug.	45

It will be of interest to start at the upper state in the Ohio River drainage basin—Pennsylvania—and to point to some of the outstanding types of difficulties found in this 6-state territory, covering the major parts of the Ohio River-Potomac River watershed.

PENNSYLVANIA

Public health work has been stimulated in this state on account of the drought. The Secretary of Health, Theodore B. Appel, M.D., dispatched Pennsylvania's 5 completely equipped automobile laboratories, which are usually used for field stream pollution investigations, into all parts of the state to assist cities, towns, and rural communities in obtaining safe water supplies. These started their work in July,

and in the next critical 6-months period, 5,000 public and private water supplies were examined in 40 counties. Federal aid was made available in March, 1931, and the drought relief work still goes on.

In 48 counties in Pennsylvania, more than half of the state, 125 cities and towns were obliged to use auxiliary or emergency water supplies, or both. The State Health Department feels that the unusual effort to keep emergency water supplies safe was responsible for the fact that no increase in typhoid fever was noted.

Howard E. Moses, Assistant Chief Engineer, State Health Department, summing up some of the outstanding experiences in Pennsylvania in 1930, quotes Kendall Hoyt,¹ to the effect that 1930 by a small margin was drier than any previous extended drought, but those in 1881, 1894-1895, and 1910 were comparable in extent, rainfall deficiency, and attendant heat. The western portion of Pennsylvania suffered most, and L. S. Morgan, District Engineer in that area, summarizes a few of the chief water supply difficulties experienced in that section, the seat of the bituminous coal fields, for which the acid mine drainage, with little or no dilution, was largely responsible. He gives the following 7 effects of the highly acid, very hard water on filter plant operation:

1. Inadequate capacity of chemical feed equipment
2. Production of abnormal quantities of sludge
3. Inadequate sedimentation basin capacity
4. Inadequate facilities for sludge removal
5. Shortened filter runs
6. Increased cost of treatment
7. Failure to reduce hardness to satisfactory point to send into city mains

In one emergency at Apollo, Pa., the Kiskiminitas River, a highly acid stream, had to be used, and a hardness of 1,900 p.p.m. was recorded. The water plant was designed to handle only 300 p.p.m. hardness; hence the difficulties are obvious.

One particular feature was noted at Pittsburgh and other cities in Western Pennsylvania when the drought finally broke, namely, the inability to hold a residual chlorine in the water, for the chlorine demand far outstripped the range of the disinfection equipment. The characteristic "rivery" taste, one of mouldy, musty nature, started to prevail along the Ohio in Western Pennsylvania and continued down to the mouth of the river at Cairo, Ill. All efforts to counteract it failed, except possibly activated carbon treatment.

MARYLAND

This state experienced the greatest deficiency in rainfall of any state in the 1930 drought. The damage to agriculture was tremen-

dous, the State Agricultural Extension Service estimating a 40 million dollar loss to farmers with a fire loss of approximately $\frac{1}{2}$ million dollars. Herds of cattle were often seen lying in groups in the fields exhausted by the lack of water. Maryland had 23.4 inches of rainfall as compared to a normal of 41.8 inches annually.

There were several outstanding results of this drought. The public water supply for 56,000 people living in towns and cities on the outskirts of Washington, D. C., failed entirely. These communities are supplied by the Washington Suburban Sanitary District, the water coming from storage and filter plants on the Anacostia River, consumption being approximately 3 m.g.d. In July these reservoirs were very low and late in the month connections were made with the District of Columbia water system.

Mention should be made of the observations of Tarbett and Frank, of the U. S. Public Health Service, that while the last dregs of water were being drained from the Anacostia storage system, with considerable algae present and the river very low, many families using this water experienced what appeared to be the same type of dysentery or intestinal disorder which prevailed later in West Virginia and in the Ohio River cities of Louisville and Ashland, Ky., and Cincinnati and Portsmouth, O., when the Ohio was flushed out in November and December, 1930. While many families living in the fringe of towns about the District of Columbia had this trouble, there was no evidence of it in the District itself in July and it completely disappeared when the District of Columbia water supply was substituted.

Water Supplies Destroyed by Salt Water—Another notable effect upon water supplies located along streams discharging into coastal waters was the encroachment of the saline waters upstream. This was observed in Maryland, Pennsylvania, and Virginia, and caused the abandonment of certain public water supplies for domestic and drinking purposes.

Havre de Grace and Perry Point, Md., watched the salty waters diffuse up stream, increasing the salinity from 7 p.p.m. in May to 200 p.p.m. in September, reaching a maximum of 885 p.p.m. in December.

Chester, Pa., on the Delaware River, and certain Virginia cities also had their public water supplies affected in this same manner. The State of Pennsylvania eventually received an appropriation of \$50,000 during the 1931 term of legislature to study further the salinity of the Delaware River and its possible future effect upon the public water supplies of Chester and Philadelphia.

Unusual Fish Mortality—The salt content in the Chesapeake Bay and its tributaries was greatly affected by the great drought of 1930.

Unusual fish mortality was reported in the Magothy and Severn Rivers and the Department of Zoölogy of University of Maryland made careful studies of it. Dead and dying fish appeared in great numbers, and the dying fish were observed swimming about breaking water with their mouths and pushing their heads upon shore, ordinarily an indication of oxygen deficiency or high pollution. These disturbances took place about November 5, and continued for about 2 weeks. The conclusions of the Department of Zoölogy were that the salt invasion was responsible for the fish mortality since there were no unusual conditions of pollution, temperature or oxygen content.

In connection with this it is of interest to note that during November and December, 1930, and January, 1931, similar effects on fish were observed in the Kanawha and Ohio Rivers at Charleston, W. Va., Ashland, Ky., and Portsmouth, O., which occurred when tastes in public water supplies were bad and outbreaks of intestinal disorder prevalent. The water in these streams may have contained some unusual chemical substance from decomposition products.

OHIO

Ohio suffered grievously in the southeastern sector. Cities depending upon storage saw the reservoirs entirely dry up and the state sanitary engineers took charge of the emergency relief work. Abandoned mines and drilled wells saved the day.

One of the relief measures in Southern Ohio was the authorization by the 1931 legislature of the expenditure of \$10,000 for extending the scope of the "Seal of Safety" wells located strategically along the highways to serve both tourist and farmer. This work was to be done by the Sanitary Engineering Division of the State Health Department. Sixty-five wells are now being drilled at a cost of approximately \$150 each. During March, 1931, a warning was sent out to all public water supply managements that 1931 had the appearance of a drought year so far as ground water supplies were concerned, for the level of the ground water had fallen from 3 to 7 feet and was still going down.

Ohio has many cities located on the Ohio River opposite the states of Pennsylvania, West Virginia, and Kentucky, and it will be of interest to note the types of weapons employed by the trained chemists in charge of modern filtration plants using the Ohio as the source of public water supply.

When the Ohio finally began to flow in late December, 1930, and January, 1931, the troubles predicted a month previous by the Ohio State Health Department engineers materialized. A musty, rivery, nauseating taste persisted in both raw and purified water despite all

efforts to remove it. Bellaire and Ironton, O., shifted over to excess lime as a disinfectant, discontinuing chlorination. Delaware, O., on a tributary, used potassium permanganate successfully for 3 days.

Warren, Marietta, East Liverpool, Pomeroy and Cincinnati, O., used the ammonia-chlorine process, which was successful in preventing phenolic tastes but did not overcome the disagreeable "rivory" taste which predominated. Great difficulty was encountered in maintaining a residual chlorine at Warren, on the Mahoning River, due to some unusual condition in the water—high organic content possibly. In one case 7 lb. per m.g. failed to show a trace of residual chlorine.

At certain other cities—Chesapeake, O., furnished water by Huntington, W. Va., and at Newcastle and South Pittsburgh, Pa.—the use of activated carbon was successful in removing the rivory, musty taste. Approximately 50 lb. of Nuchar per m.g. were used. The treatment costs approximately \$4 per m.g.

Ohio River Cities Experience Sickness—In a paper presented by F. H. Waring, Chief Engineer of the State Health Department of Ohio, before the Indiana Section A. W. W. A. in February, 1931, mention is made of the widespread complaint about the water in Cincinnati and the Ohio River cities of Ironton and Portsmouth because of objectionable tastes which were accompanied by an outbreak of so-called "intestinal influenza." Two theories were advanced by medical men: that a type of influenza prevailed affecting the intestinal tract; and that there was a toxic property in the river water by reason of the decomposition of organic substances of vegetable and animal origin.

Bacteriologically, the public water supplies where these intestinal disorders prevailed met the U. S. Treasury Standards of safety. The State Health Department has taken the stand that it does not know which theory is correct but such a situation warrants the expenditure of considerable funds by a city water department either to purchase or install equipment, or for the purchase and use of additional chemicals in the water treatment.

The result of the Ohio experience on the whole is that these Ohio River cities are now installing or considering the installation of ammonia-chlorine or activated carbon equipment in order that they may be able to cope with any type of tastes, drought or no drought. New ideas on water treatment have been evolved as a result of the drought and the practical remedies should be applied.

KENTUCKY

At the peak of the drought in Kentucky, one-third of the public water supplies of the state were forced to adopt emergency measures.

The far famed Kentucky blue grass section was scorched brown, and water became a very precious article. One might characterize the city water supplies of this section as "transported water supplies," for this limestone area depends upon storage reservoirs and these had become bone dry.

Shelbyville, 30 miles from Louisville, drank the Louisville water. It was hauled in by means of sixteen 10,000 gal. railroad tank cars daily from August 7, 1930, to February, 1931.

Richmond, after using up 245 m.g. of stored water and a private lake with emergency chlorination, began shipping 210,000 gal. of water daily on the L. & N. Railroad from Valley View.

Lexington was threatened in September when the 1,640 m.g. storage became low, and rushed to completion a 6½ mile emergency line to the Kentucky River which was completed in record time.

Louisville had an ample supply of water but was bothered by an unusual biological condition. The Ohio River, though green and clear, had an algal and plankton content of many thousands per c.c. instead of hundreds, as is normally the case. Despite all types of treatment the water remained unpalatable and was not satisfactory as a beverage.

The significant public health note in Kentucky during the drought was the action of the State Health Department in sending out anti-typhoid vaccine to approximately 1 million people. People were drinking water from all sorts of places and therefore this wholesale immunization was deemed advisable. Nearly ¾ million people were thus protected.

In December, 1930, and January, 1931, came a widespread epidemic of intestinal disorders in Louisville which was investigated by M. V. Veldee, M.D., of the U. S. Public Health Service, who had earlier reported upon an intestinal outbreak of rather large proportions at Charleston, W. Va., on a tributary of the Ohio River.

WEST VIRGINIA

Next to Maryland, West Virginia had the least rainfall of any state, 59 per cent of the normal. The wheels of industry were stopped in some sections by complete disappearance of streams. The Tygart Valley River in the northern part of the state, 1,340 square miles drainage area, was reduced to a flow of 1.5 cu. ft. per second.

The Elk River, 1,550 square miles drainage area, which is the source of water supply for the capitol city, Charleston, dried up for practical purposes and an unprecedented case of intense pollution and a serious public water supply emergency were created by reason of the Elk River flowing up stream carrying gross sewage and garbage pollution from its junction point with the canalized Kanawha River.

Charleston, with a privately owned water supply, tried all resources to get rid of the objectionable, nauseating odor, but to no avail. The bacteriological counts of the filtered water were satisfactory but the sewage and garbage, organic pollution was too great, producing a nauseating taste and odor which persisted all summer, reaching its worst in late October, 1930.

Early in November 5,000 to 8,000 people living in the city of Charleston suffered from temporary intestinal disorders characterized by a sudden onset, pain in the region of the stomach, usually nausea or vomiting or both, and followed by diarrhea of varying severity. People flocked to bottled waters and miscellaneous springs and wells. The state health authorities were assisted in their investigations by R. E. Tarbett, Sanitary Engineer, and M. V. Veldee, M.D., epidemiologist of the U. S. Public Health Service. The following conclusions were reached:

1. Too gross pollution existed at the regular water intake due to back flow from the sewage zone.
2. The raw water in the stream had zero dissolved oxygen at times.
3. The raw water count was excessive—200,000 per c.c.
4. The *B. coli* content of 10,000 per c.c. was too high for safety.
5. The organic matter, algae and protozoa were extremely high, calling for a 20 lb. per m.g. chlorine dosage to supply the chlorine demand.

An emergency water intake in the Kanawha River was proposed and on November 11 approved, and construction started, work being completed in January, 1931, just before the heavy rains came.

Intestinal disorders were also noted at another West Virginia city—Weston—where the raw water was grossly polluted due to heavy sewage concentration. Here also nauseating, musty odors and tastes prevailed. Another Ohio River city—Sistersville—gave a record of a large number of cases of intestinal disorder, coincident with the bad taste troubles in the late fall months.

With the Charleston, Weston, and Sistersville records of intestinal disorders of many thousand people in these 3 cities on file, and the epidemiological evidence indicating that it was in some way connected with the public water supplies—even though these were purified in modern plants and gave a safe bacteriological test—it would appear that research should be undertaken to show whether a heavy organic or algal load on a water supply may in any way affect the health of the consumers.

Stream pollution in West Virginia has been brought into the spotlight by these unusual experiences and the new State Water Commission, created by the legislature to handle these problems, is expected to

make some definite decisions which will limit sewage and industrial pollution and start a reclamation program.

VIRGINIA

The water supply conditions in Virginia called for continual alertness on the part of the Sanitary Engineering Division to cope with rapidly developing emergencies. The far famed and productive Shenandoah Valley lay parched and brown from May until December, with the rural communities suffering most from loss of crops. Eighteen cities and towns had to adopt emergency measures, and the records of the State Health Department show the following large amounts spent to get water:

COST OF VIRGINIA EMERGENCY WATER SUPPLIES

Newport News	\$83,000
Front Royal	19,000
Harrisonburg	27,000
Bluefield	40,000
Staunton	8,000

The types of difficulties in Virginia were much like those developing in the limestone areas of Kentucky, for the territories are much the same, depending largely on impounded supplies in the mountains. Many emergency hypochlorite disinfection plants were set up and all emergency supplies were heavily treated with "H. T. H."

Chlorination of emergency supplies was one of the major means of protection. A unique means of relief was adopted at the Marine Base at Quantico, where salinity entered the picture. Quantico, supplied from Chapawansic Creek, saw this creek go lower and lower until the water works could only be operated intermittently. Then, barge service was commenced, filtered water being taken on at Norfolk and Indian Head. The barges leaked salt water in some cases and entire loads that were too high in salinity had to be wasted. In tidewater, Virginia, the salt water diffused further up stream than ever known before—16 miles up the Potomac—and had a marked effect upon the aquatic life in the rivers. On the whole the section of Virginia suffering most lay between the Blue Ridge Mountains and the Allegheny and here the major amount of emergency relief work had to be done.

SUMMARY OF TYPES OF TROUBLES

Reduced Stream Pollution—One outstanding and persistent trouble in all affected states was the prodigious algal growth in streams and storage basins with the accompanying organic load and the resulting nauseating tastes and odors. In many cases there were no known means of relieving the condition.

The series of 53 artificial lakes in the Ohio River between Pittsburgh, Pa., and Cairo, Ill., into which sewage and industrial wastes poured, and from which there

was almost no flow except by displacement by polluted water, constituted basins where pollution progressively increased throughout the summer months. It is no wonder that it was difficult to treat water from these basins so as to make it potable even in modern purification plants.

The "Great Drought" has warned the people of the Ohio drainage basin that pollution of their river has reached the limit and that the coöperative principle successfully carried out by the 11 states on the basin in eliminating phenol, a damaging trade waste, should be extended to other industrial and to sewage wastes. The Interstate Stream Conservation Agreement of 1924 should without delay be enlarged in scope to reduce stream pollution on this great waterway.

Taste and Odor Control—Research work has been stimulated by the drought along the lines of taste and odor control, and the principles being developed in the laboratory were given an extensive application over the eastern part of the United States. Oklahoma lists 12 cities which have adopted ammonia chlorine control of tastes and odors since January, 1931. Ohio, West Virginia, and Pennsylvania now have many plants equipped with both ammonia-chlorine and activated carbon treatment units and it seems likely that these processes will soon be incorporated into routine plant operation nearly everywhere.

Intestinal Disorders Show Need for Further Research on Heavy Organic Loads with Algae—The several instances over this drought area where definite intestinal disorders have appeared associated with bad tastes and heavy organic loads cannot be overlooked. The towns and cities around Washington, D. C.; Charleston, Weston and Sistersville, W. Va.; Ashland and Louisville, Ky.; and Portsmouth, Ironton and Cincinnati, O.; all testify that something unusual in the way of intestinal disorders appeared during the drought, and it may be that algae in heavy concentrations with the resulting organic load may be a factor in bringing about these troubles.

It is significant that Charleston, W. Va., on the Kanawha River, where the organic load on raw water was heaviest, as evidenced by a chlorine demand of approximately 20 lb. per m.g., experienced the most severe type of intestinal disorders, while Ohio River cities where there had not been the opportunity for such tremendous putrefaction of organic matter were not so severely affected. An unusually close check was maintained at Charleston upon the bacteriological quality of the effluent so that a water meeting the U. S. Treasury Standards for safety was delivered at all times.

R. F. Goudey,² Sanitary Engineer, Department of Water and Power, Los Angeles, Calif., in discussing sewage reclamation in the Los Angeles Metropolitan area, mentioned the possibilities of using purified sewage as a source of public water supply in the following words:

"When sewage has been completely treated in a super-activated sludge plant and is then put through the entire gauntlet of water purification, why should it not be used directly for domestic purposes? Why should its reinstated purity be lost by using the water for *less noble* purpose?"

When we have these unexplained evidences of a severe intestinal irritant as evidenced in the cities of the Ohio River basin during the drought, we should find the answer before the adoption of reclaimed sewage for drinking purposes.

Salt Water Invasion of Water Supplies—Public water supplies on the coastal rivers in Pennsylvania, Maryland, and Virginia were affected by the diffusion of salt water up stream. On the Susquehanna it came up 30 miles and on the Potomac

16 miles. Certain water supplies in Maryland had to be discontinued on account of the salt content. In Pennsylvania the legislature made available \$50,000 for a complete study of this phenomenon, since it menaced the public water supplies of Chester and Philadelphia. The salt water invasion had a secondary effect, according to investigations by the Department of Zoölogy of the University of Maryland, their studies indicating that the high saline content in the Magothy and Severn Rivers was responsible for the very extensive death of fish.

Ground Water Lowered—Ground water supplies have been lowered throughout the drought area and no recovery has been made to date in 1931. Well and spring supplies will probably fail in sections of all 6 drought states during 1931, since the water table is several feet lower than at the corresponding time of 1930. This condition in West Virginia had developed increased mineralization in deep well supplies, and iron particularly is giving much trouble.

In Ohio the threatened lowering of ground water has been responsible for the action of the 1931 legislature in making available \$10,000 to drill and equip 65 wells in Southern Ohio to supply farmers and tourists with safe drinking water.

Typhoid and Intestinal Disorders—There was no large increase in typhoid fever in this area in 1930 such as was observed in the 1925 dry period. Possibly the wholesale typhoid immunization indulged in because citizens wished protection was one reason. Then too, state sanitary engineering divisions were unusually active in supervising the chlorination of emergency water supplies.

Stream pollution control work and its needs have been emphasized and the program may be expected to go ahead more speedily. Taste and odor control by treatment with ammonia-chlorine and activated carbon has received a strong stimulus and it appears likely that processes until now considered in the research stage will move rapidly to the field of practical application.

It has been reasonably well proved that too great an organic and putrefactive load of pollution on a raw water supply will bring about conditions which may cause intestinal disturbances among the users even though it meets the strict bacteriological qualifications for a safe public water supply.

The aggregate and final effect of the 1930 drought on public health will probably be beneficial. The general public have received a dramatic portrayal of the worth of safe, palatable, adequate public water supplies.

DISCUSSION

H. E. MOSES

Assistant Chief Engineer, Pennsylvania Department of Health, Harrisburg, Pa.

MR. TISDALE in his excellent paper has graphically portrayed the desperate condition in which public water works found themselves in the affected area. Merely to procure a water supply of any sort to replace or supplement those which had failed or dwindled to the vanishing point taxed the ingenuity and resources of the water works officials. Frequently, the ordinary supplies and the emergency ones were unpalatable. Conservation measures entailed rationing of the public supply in extreme cases.

As a consequence, the public resorted to the use of miscellaneous supplies secured where possible and without due regard to their safety. A serious health problem thus arose, entirely distinct from the necessity of rendering safe the public supplies.

In Pennsylvania, a measure designed to meet this condition was instituted by the Secretary of Health, who kept 5 mobile laboratories in the field from August, 1930, to September, 1931, except for the mid-winter months. From March, 1931, federal aid was given. Each unit was in charge of a sanitary engineer, the remaining personnel comprising a bacteriologist and laboratory helper and 3 health officers. The service was free to anyone desiring it. Work was principally confined to the rural areas, although upon occasion examination was made of public supplies, especially where emergencies occurred. At one place where the public supply was in serious trouble, the townspeople drove far from town to secure water and here nearly 800 samples were collected over a 20 mile area. At its conclusion this work had been carried on in 44 counties, and nearly 23,000 water supplies had been examined.

Perhaps the drought was needed as a lesson to the water works fraternity and public health engineer. We have become so accustomed to thinking with rather smug satisfaction that our water supplies in general are safe, adequate, and mostly palatable, that some sharp lesson is required to show the narrow margin which really exists between such a state and one where the ordinary routine is endangered and all the potentialities engendered by emergencies spring into being. That the affected area was not visited by a marked increase in water-borne disease is a gratifying commentary on the extreme care with which the safeguarding of the innumerable water supplies which had to be used was carried out, many times under adverse conditions.

New methods of treatment of water supplies for the control of odors and tastes probably advanced, under stress of immediate needs, far more rapidly than would ordinarily be expected. What usually would require months and perhaps years to accomplish has happened over night because of the urgent need of some means of producing water fit to drink. At the close of 1930, 17 water works in Pennsylvania had installed the ammonia-chlorine process, and other installations have since been made. Activated carbon has been tried out and in at least one instance adopted as a regular plant process when needed.

As the result of failure of impounded supplies, the water works engineer is asking the pertinent question as to whether we need to revise our present-day basic design figures as to storage.

Naturally where large impounded supplies were used there was a distinct lag in feeling the effects of the drought; this in distinction to the smaller supplies which were early in trouble. In Pennsylvania in the case of 2 large water works with immense storage reservoirs in use, serious trouble was not encountered until the end of 1930, whereas the smaller supplies were depleted in August. There is one instance of a 3 billion gallon reservoir drawn down to 19 per cent of its effective storage, and there are still other instances of where very large impounding reservoirs were practically emptied. Consequently, it is no wonder that the engineers of these water companies are giving consideration to the matter of the possible need of additional storage.

Pertinent to this subject is an article by Kendall K. Hoyt¹ where in a discussion of data compiled by the U. S. Geological Survey on the 1930-1931 drought he says:

Droughts Recur—Studies of past rainfall and stream-flow records show clearly that droughts are recurrent and that another drought of 1930 severity is almost mathematically certain to happen again. Notwithstanding opinions of old residents to the contrary, the 1930 drought was not unparalleled. It was the severest in 50 years of definite record, but three others during this same period were comparable in extent, rainfall deficiency, and attendant heat: those of 1881, 1894–1895 and 1910, fifteen years apart on the average. The 1930 drought, however, was of exceptional effect not only because of the economic depression but also because the demand and uses for water have increased since the drought of 1910.

Many interesting problems have arisen due to the adverse conditions, some of which have been mentioned by Mr. Tisdale. One that seems to have been rather general was the changes which occurred in the character of the water, particularly noticeable in Pennsylvania on the Allegheny and Monongahela Rivers. L. S. Morgan, District Engineer of the Pennsylvania Department of Health, stationed at Pittsburgh, describes some of the conditions prevalent at that time as follows:

The Monongahela receives considerable mine drainage and is usually acid down to Pittsburgh and the water plants along this stream have been accustomed to handling water of that type. However, this condition changed and while the river was highly acid to a point about 25 miles above its mouth, down stream from this point the acidity was gradually decreasing until it was actually alkaline near its mouth during the extreme low flow period. This gradual reduction was not due to the inflow of alkaline diluting water from tributaries, but was caused by neutralization of the acidity, principally at industrial plants, of large volumes of the river water and the return of this alkaline water to this stream.

The increased cost of treatment was a serious factor and was due principally to the amount of chemicals used. At one water works as much as 27 tons of soda ash and 12 tons of lime a day were required to soften 14 million gallons of water. Here the cost of chemicals alone for 1930 was more than double that for any previous year. This plant has constructed a carbonization plant and will utilize the carbon dioxide generated by burning natural gas. Other examples might be cited, but this one alone is significant of the changed conditions which had to be met by water works operators.

The failure of underground water supplies has directed attention as perhaps nothing before to ground water conditions. Seemingly definite information is hard to secure concerning the replenishment of underground supplies. The general impression seems to exist that wells and springs have not returned to normal and the statement has been made by John C. Hoyt, of the U. S. Geological Survey, that while the surface streams may be expected to be restored shortly, it is anticipated that a much longer time will be needed before the wells and springs come back to normal. It has been our observation in Pennsylvania, without making a definite and detailed study, that the underground supplies have not been replenished although they are not so seriously affected as during the 1930 drought.

One interesting case was noted which might have some significance. A limestone quarry was visited during August of this year. This has a depth of possibly 60 feet and when seen was quite dry. The department's engineer was told that this quarry had been dry for the last 18 months, whereas formerly it had been necessary to pump water at a rate at times as high as 500 gallons per minute.

It is not particularly relevant in this discussion to refer to other phases of the drought, such as the effect on crops, but because of the relation between forest cover and runoff, it is at least interesting to mention the effect which the drought had in the forests. One brief reference to this will serve to illustrate this phase of the

problem and is quoted from the *Service Letter*, Pennsylvania Department of Forests and Waters, April 16, 1931, as follows:

LOSS IN TREE GROWTH FROM THE 1930 DROUGHT

Measurements and observations taken on the Mont Alto and Michaux State Forests in Franklin County indicate that the tree growth of 1930 was 25 per cent less than that of 1929, as a result of the drought. White pine showed a loss in diameter growth of 28 per cent. Similar conditions were observed in the Rothrock District in Huntingdon County and in the Penn District in Mifflin and Centre Counties.

On the basis of an average growth of 40 cubic feet per acre per year, the 1,429,135 acres of State Forests suffered a loss of 14,290,000 cubic feet or 158,700 cords. On the basis of an average growth of 25 cubic feet per acre per year, the 13,206,000 acres of forest land in the State suffered a loss of 82,538,000 cubic feet. In addition, thousands of forest tree seedlings have died as the result of the drought.

Who Are the Superior?

AT the same time that I do not consider the proofs of the inferiority of the rapidly reproducing groups satisfactory, I do not consider the proofs of the hereditary superiority of the socially successful satisfactory. Social success, in which I include economic success, is proof only of individual adaptation to the conditions necessary to secure the type of success which happens to be valued most highly by the group at a given time. It is not proof of an all-round ability in the person who succeeds, nor is it proof of the possession of qualities which will contribute largely to the development of a progressively improving society. As a matter of fact, many people who make a social success do so because they are thick-skinned and lack the imagination to see the ways in which their success will react adversely upon the welfare of others and upon the organization of community life. There is nothing inherent in the nature of social success to ensure that the person who attains it will also possess the finer human qualities which will add to the fullness and richness of our life.

It would not be at all difficult for any one who knows a number of successful people to pick out several of them, perhaps one-tenth to one-fourth, who owe their success largely to the qualities which they share in common with the bully, the prize fighter, the ward heeler, and the fox.—Warren S. Thompson, *Population Problems*, 1930, p. 355.

Sewage Disposal Difficulties Due to Drought*

LEWIS S. FINCH, C. E.

Chief Engineer, State Board of Health, Indianapolis, Ind.

IN considering the difficulties occasioned by a drought, in relation to sewage disposal, one has an entirely different point of view from that of the water works man with a surface supply who is likewise in trouble from the same general cause. In a given situation there normally may be sufficient water in a stream to furnish an adequate water supply and also sufficient dilution for the sewage of the community as it is discharged to the stream, either with or without treatment. At times of low water stage, except when the raw water supply is affected by upstream sewage discharges, the difficulties in connection with the disposal of sewage will arise before a water shortage makes itself felt. In fact there may be serious difficulties in connection with the disposal of sewage with no shortage of water for water supply purposes.

On the surface at least, the effects of a drought, in a given case, may serve only to create conditions in a relatively unpolluted stream which are similar to grossly polluted conditions frequently occurring in a nearby stream. For that reason, a drought does not present the unusual circumstances in relation to sewage disposal that it does with respect to water supply.

In the drought area during the first season of the 1930-1931 drought, lack of normal surface run-off caused low stream stages. During the second season the stream flow stages were further affected by failure of the ground water resources which are normally available for maintaining minimum stream flows in the absence of surface run-off.

Table I taken from *Engineering News-Record*¹ indicates the degree of shortage during 1930 in certain major Ohio streams. Data presented on 5 West Virginia streams² indicated essentially the same stream flow conditions to be prevalent in that state.

It is obvious, if the flow in a stream is barely adequate under ordinary circumstances to furnish proper dilution for the sewage of a community, that if the flow falls to only 5 per cent of normal, for example,

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

the otherwise relatively unpolluted stream will become grossly polluted.

Such conditions undoubtedly existed at many points in each of the states within the drought stricken area but with more serious effects in certain localities than others. An analysis of the effect of drought in relation to sewage disposal may indicate that under certain circumstances a drought may be helpful rather than detrimental to stream conditions. Further than that, circumstances so alter cases with respect to stream pollution problems that specific instances of exceptions to broad principles may always be found.

In the present discussion, no attempt will be made to describe specific instances of difficulties encountered except in cases where such an instance may serve as an example of the circumstances being outlined. Instead, the writer will present briefly the general circumstances under which difficulties occur, the broad effect of the difficulties, and the general remedial measures which would be helpful if they could be applied.

EFFECT ON SEWAGE DISPOSAL

Outside of those conditions common to all streams overloaded with sewage, the low river stages accompanying a drought are responsible in many cities for exposed sewer outlets with accompanying local nui-

sances. Under normal circumstances such conditions would not be tolerated, but under drought conditions which everyone feels may be terminated at any time they are allowed to continue.

Low stream stages also expose sludge deposits with attendant odors and unsightliness.

On the other hand, where cities have sewage treatment works drought conditions may be helpful so far as plant efficiencies are concerned. In the first place, the sewage becomes concentrated and, up to a certain point, more amenable to treatment. This concentration primarily results from lowering of ground water tables with consequent lessened infiltration into sewers. In communities where an acute water shortage exists the sewage is even further concentrated because of economy of water consumption. Increased plant efficiencies are also obtained in the case of works treating combined sewage because of less frequent disturbances due to storm water.

Sludge drying is also facilitated under drought conditions. In a properly designed and adequate plant this may not be a material factor but in cases where sludge digestion and drying capacities are inadequate the lengthened drying season may be exceedingly helpful. During the winter of 1930, the weather in Indiana was such that it was possible to dry sludge on open beds during the entire season.

EFFECT ON STREAM CONDITIONS

In first considering the result of low stream flows attendant upon a drought, it would not be expected that benefits would accrue because of the limited amount of water available for dilution. In general, however, stream conditions often are improved if the stream is considered as a whole.

In the first place, streams which in normal years may be deep, under drought conditions become shallow and partake of the more favorable self improvement characteristics of small streams. For a number of reasons small shallow streams correct polluttional conditions much more quickly than deeper ones. There is more opportunity for surface absorption of oxygen than in deeper ones, since in such streams the water is exposed to the air in thin sheets with the result that there is more exposed area in relation to the total volume of water. Under such circumstances the direct effect of the actinic rays of the sun is also more pronounced.

Under drought conditions stream turbidities usually are low since there are no rains sufficient to carry in surface wash. This latter circumstance occurs more readily after the drought has persisted for some time in that due to dry soil conditions very heavy rains often do

not cause turbid streams. Such low turbidities favor the prolific development of algae. Of particular interest in this connection is the prevalence of algae capable of photo-synthesis.

In certain shallow Indiana streams over 300 per cent saturation of dissolved oxygen has been found on sunny days. Certainly such conditions assist materially in improving stream conditions. Of course, in normal years excessive dissolved oxygen content may be expected on sunny days, but the ratio of bright to cloudy days certainly is increased under drought conditions. While, from the water purification man's point of view, such algal conditions are not considered an unmixed blessing, nevertheless on a stream not used as a source of water supply such conditions are helpful in enabling the stream to return more quickly to its natural condition after receiving a pollutorial load.

Diminished flows in many streams result in the formation of alternate pools and riffles, the pools affording opportunity for sedimentation and the riffles for surface absorption of oxygen. Again the formation of such pools may not be without its disadvantages since very offensive conditions with serious local odor nuisances may be produced by the decomposing sludge in them. Nevertheless if the whole stream is considered, in many cases conditions may be found to be better with the low flow. Even then the benefit of improved conditions may be lost if a sudden freshet quickly washes out the sludge which has accumulated in the pools over a period of months. Under such circumstances water supplies, not normally greatly affected by the discharge of sewage upstream, may be seriously jeopardized.

For the purpose of illustration, data secured during the course of a stream improvement survey of White River between Anderson and Muncie, Ind.,⁵ are presented in Table II. A review of these data indicates that the concentration of *B. Coli* at the Anderson intake was much lower during the summers of 1925 and 1930, both drought years, than during 1926, which more nearly represented normal conditions.

During drought years, due to diminished flows, less oxygen is available in the streams as they reach points of sewage discharge. This condition is further aggravated by the fact that the temperature of water in shallow streams may become extremely high, with consequent lowering of capacity for oxygen absorption. While there are no compensating factors for the oxygen deficit, nevertheless the smaller stream flow results in increased concentration of organic matter in the stream. As observed by Streeter⁶ and others, the rate of self purification of a stream is markedly accelerated in stretches where the concentration of organic material is highest. In other words, the rate of self improvement is proportional to the concentration of organic material.

TABLE II

B. Coli CONCENTRATION IN WHITE RIVER, MUNCIE TO ANDERSON

Period	Distance Below Muncie Intake Miles	Number of Days Sampled	B. Coli* per c.c.	Remarks
1925 July, Aug., Sept.	0 9 22	17	20 9,000 49	Extremely dry season with very low stream flow Anderson Intake
Oct., Nov., Dec.	0 9 22	10	10 1,000 275	Anderson Intake
1926 Jan., Feb., March	0 9 22	6	7 750 400	Anderson Intake

1930 Sept., October	0 9 14 16 22	3 3 3 3 4	4 67,000 400 100 30	Extremely low stream flow under conditions of extreme drought Anderson Intake

* B. Coli Determinations 1925-1926 by Indianapolis Water Company—10 portions each dilution, parallel planting on Brilliant Green.
B. Coli Determinations 1930 by Indiana State Board of Health—1 portion each dilution, presumptive only.

In summarizing it may be said that even though theoretically there are advantages to be attained through low stream flows, predictions as to the actual occurrence of such benefits can be made only when certain definite circumstances are considered. This is the case since there may be improvements at one point on a stream, while at other points a corresponding increase of undesirable features may be noted. Perhaps the best example of what may happen due to diminished stream flow may be seen in the case of Charleston, W. Va.² This city is located at the confluence of Elk and Kanawha Rivers. The

Kanawha is the larger and is canalized. The water supply intake is located in Elk River at least $1\frac{1}{4}$ miles above the junction. Downstream from the intake on the Elk, the city is said to have maintained a garbage dump. The municipal sewers discharge into both the Kanawha and the Elk but none above the intake.

As the river flow diminished during the summer of 1930, due to the dams in the Kanawha, the Kanawha and lower Elk became one great septic pool. On July 24 the flow in the Elk became less than the draft placed upon the stream by the water works and consequently the water from the pool, containing the garbage dump and an accumulation of sewage, was drawn upstream to the intake. Very soon the dissolved oxygen of the raw water fell to zero and the 37° bacterial count rose to between 50,000 and 100,000 per c.c. with organisms of the *Coli-aerogenes* group demonstrated in 0.001 c.c. In addition other organic substances had built up to a concentration which made it impossible for the purification plant to produce palatable water although by careful treatment it was made safe—at least from a bacterial standpoint. The same general circumstances occurred at another major city in the drought area.

Low stream stages with consequent complications in relation to sewage disposal affect the general public welfare in many ways. Fish life is materially interfered with and in many cases is actually destroyed with attendant economic loss from the food standpoint to say nothing of the effect upon the activities of sportsmen. The use of streams for watering stock is materially interfered with. The water also is in some circumstances rendered unfit for industrial use. By the formation of pools with consequent accumulation of sludge, and in many other ways, drought conditions in streams result in extremely objectionable odors which materially injure the comfort of those living nearby. However the greatest detriment is the deleterious effect upon public health.

In the first place exposed sludge deposits and the like may result in an extreme fly nuisance. Milch cattle may wade in polluted streams and come out for milking with bits of scum and sludge adhering to the flanks and udders. If the cow is not prepared for milking with extreme care, this sewage material may find its way into the milk.

Of far more importance however are the difficulties experienced in connection with the operation of water purification plants. The outstanding example of such trouble occurred in connection with the Charleston, W. Va., water works. The circumstances there in the summer and fall of 1930 have been described but the direct effect upon plant operation was not touched upon. As has previously been indi-

cated it was possible to make the water safe from the bacterial standpoint by careful operation and heavy chlorination but nauseating tastes were experienced.

Prechlorination² at the rate of 4 p.p.m. assisted in reducing the bacterial load; copper sulphate applied every other day to the river reduced algal growths; aeration restored the dissolved oxygen to some extent but the resulting product was described as "vile." In further efforts to abate the tastes, superchlorination, pre-ammoniation, and the use of powdered activated carbon was practised with some alleviation but not correction of the tastes.

In spite of the fact that the water was demonstrated to have been bacterially safe, a city-wide outbreak of gastrointestinal troubles occurred. Inasmuch as the characteristics of the outbreak were typical of a water-borne epidemic, and the water was above suspicion from the bacterial standpoint, it was decided that the difficulty was probably of chemical origin and that the causative agent possibly was one or more of the end products of the excessive organic decomposition which had taken place in the water.

A similar outbreak occurred during the winter of 1930 in practically all cities taking water from Ohio River as far down stream as Louisville, Ky. In these cases the epidemic was usually city-wide and seemed to have been typical either of water-borne or so-called influenzal outbreaks. At the same time very objectionable "river tastes" were present in the water supplies drawn from this portion of the river. Conditions in Ohio River were somewhat similar to those experienced at Charleston in that the river is canalized and had been at pool stage for many months. While somewhat similar outbreaks of gastrointestinal disturbances were prevalent throughout the Ohio Valley, in cities drawing water from wells as well as from streams, M. V. Veldee, M.D., of the U. S. Public Health Service, made an epidemiological study of the outbreaks along Ohio and decided that they probably were water-borne, and possibly due to the heavy concentration of decomposing organic matter in the streams.

As in the case at Charleston, many different expedients were tried in an attempt to combat these tastes. Powdered activated carbon, pre-ammoniation, and other methods were employed at various plants with varying degrees of success.

While such tastes and odors of themselves probably have little direct effect upon public health unless they are associated with decomposition products capable of causing sickness, nevertheless, indirectly they may cause people to drink water from unknown sources which may be dangerous. Objectionable tastes may be attributed to the

use of chlorine, and for that reason in improperly controlled plants the use of the chemical might be discontinued or decreased in quantity, thus establishing conditions causative of water-borne disease.

Heavy burdens may also be placed upon purification plants because of a concentration of organic matter including bacteria. Such excessive concentrations may be caused directly by lack of dilution, or by a washout of organic material which has accumulated in the stream over many months. Back flow of sewage laden water in a manner similar to that at Charleston might quite easily cause a break in purification with attendant sickness.

Measures necessary to prevent such difficulties may be taken in relation to sewage treatment, water purification, or stream control.

In designing sewage treatment works liberal allowance should be made in the type and extent of treatment adopted in order to provide a margin of safety for unusual weather and stream conditions.

Treatment works should be carefully operated at all times but especially during low stream flows.

At such times under special circumstances the use of chlorine may afford some measure of relief, for reduction in biochemical oxygen demand results from sewage chlorination.

Chlorination of a sewage treatment plant effluent may also serve to delay decomposition in the receiving stream until a nearby tributary can supply diluting water. It may also serve to delay decomposition until critical down stream points have been passed.

The real solution to the problems discussed in this paper is more rain, or at least more water in our streams. In the present stage of our knowledge nothing can be done about the rainfall deficiencies but to a certain extent stream flow could be controlled. In this case the same remedy lies for increasing minimum flows as for controlling flood flows, namely, the construction of upstream storage reservoirs and the carrying out of reforestation programs wherever possible. If storage reservoirs were available flood flows could be decreased and minimum flows increased. The same results in a minor degree would be accomplished by reforestation.

Careful education of the public and officials by sanitary engineers and public health workers will be necessary before the latter expedients can be carried out.

An Epidemiological Study of Suspected Water-borne Gastroenteritis^{*}

M. V. VELDEE, M. D.

Surgeon, U. S. Public Health Service, Washington, D. C.

LATE in October, 1930, there developed among the inhabitants of Charleston, W. Va., an acute ailment involving the gastrointestinal tract. Without any prodromal symptoms the attacked individual suffered an acute disturbance in the alimentary canal, beginning usually as a sharp pain in the epigastrium with general abdominal discomfort, the severity varying a good deal with the individual. Nausea or vomiting or both soon followed. In the milder cases no further symptoms developed, though in the vast majority diarrhea ensued within a few hours. In the severe cases the diarrhea became an uncontrollable bowel action over a period of several hours. There were no known cases which developed bloody stools. The site of greatest irritation varied with the individual, so that in some vomiting was the most annoying symptom, in others abdominal cramps, and in yet others a diarrhea, while the more severe cases developed all the symptoms mentioned.

In relatively few instances was a physician consulted, so that clinical observations were limited. A few temperatures had been taken and these were practically normal in the robust adult, but usually slightly elevated in the aged, the enfeebled and in young children. One of the physicians interviewed had made one or two white counts and found them within the normal range.

The duration of the attacks rarely extended over three or four days, with the milder ones lasting only a few hours. With the subsidence of the symptoms the patient again felt entirely well, except for such general weakness as may follow the use of any strong purgative.

The writer investigated this outbreak on November 12 and 13 at which time very few new cases were developing. State health officials estimated that in Charleston's approximately 60,000 inhabitants there had been from 4,000 to 7,000 cases. There had been no deaths. A house-to-house inquiry was made of homes in two rather small areas of

^{*} Read before the Public Health Engineering Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

the city; one being in an economically good section and the other in an economically poor section. The former reported 11.4 per cent of all persons canvassed as having been ill, while the economically poor section reported 18.7 per cent. This gives approximately 9,000 cases for the entire city.

No reports had come to the State Department of Health of cases occurring elsewhere in the state. The Kanawha County Health Officer had encountered no cases in that portion of the county beyond the city boundaries of Charleston. At the writer's request the County Health Officer talked over the telephone with practising physicians in those communities lying in the general vicinity of Charleston. Each physician stated that he had no such disease in his practice nor did he know of any in his community. Inquiry was made more particularly among those families living across the Kanawha River from Charleston. No cases had appeared among them.

The outbreak in Charleston soon abated and no further disturbance was encountered until near the first of January, when cases with exactly the same symptomatology began to appear in Huntington, W. Va., and Ashland, Ky. It was the opinion of the Health Officer and physicians of Ashland that the number of cases in that city began to decrease about January 10 so that at the time of the writer's visit on February 3 few if any cases remained. Many physicians in Ashland were interviewed and all gave the same clinical description which coincided with that already given for the Charleston cases.

Investigation revealed that residents of Ironton, O., had experienced the same ailment at approximately the same time as those of Ashland. Portsmouth, O., reported the same experience though apparently in a less severe form. Cases began to appear in Cincinnati about January 15 and rapidly increased in number, though it was apparent by February 1 that few new cases were developing. The exact number occurring in Cincinnati cannot be stated, as no systematic canvass was made and cases were not reported to the health department. However, in view of comments appearing in the press, conversations overheard in various meeting places, and the fact that personal conversations with many individuals in various economic positions revealed few who either had not suffered from the ailment themselves or had relatives or friends who had been afflicted, it must be concluded that a considerable percentage of the population was attacked, though it is believed this was not so great as in Charleston.

Complaints from Louisville, Ky., about January 25 indicated that that city was experiencing the same inconvenience.

A personal investigation was made in Hamilton, Dayton and Co-

lumbus, O., and Parkersburg, W. Va., without finding any evidence of a similar outbreak in these cities. Indirect information from Pomeroy, Marietta, Bellaire, Martin's Ferry and Steubenville, O., and Wheeling, W. Va., indicated that no cases had come to the attention of the officials in any of these cities. Similar information from a non-medical source was that cases were appearing in Sistersville, W. Va., about December 20, though this was not confirmed. The most striking illustration is that of Cincinnati and Norwood, O. The latter city, with a population of 33,000, is so situated as to be almost entirely surrounded by the city of Cincinnati. The available evidence indicated that numerous cases did occur in Cincinnati, but through a similar investigation in Norwood the writer was unable to find cases among that portion of the population which had had no direct contact with Cincinnati. A large portion of the working population of Norwood is employed in Cincinnati and among this group cases did occur.

Unfortunately a more detailed case investigation could not be made throughout the epidemic zone. Because of the relative mildness of the disease, cases were not referred to hospitals for treatment. For this same reason, and also because of the explosiveness of the outbreak, the physicians did not have time to make any clinical study of the cases. One visit to the physician or a request for advice over the telephone usually sufficed for the relatively small portion who sought medical attention. However the present epidemiological investigation was sufficiently detailed to outline the geographic distribution of the outbreak and provide evidence which appeared at that time to give a plausible explanation for the disease.

Approximately one-sixth of Charleston's population became ill in the brief period of 2 weeks. This indicates a rapid dissemination of the causative agent throughout the city, irrespective of economic, social or color barriers. The presence of so many cases within the city and the complete absence in the communities immediately surrounding further restricts the causative agent to some channel which did not extend beyond the city boundaries in the Charleston area; unless we are to assume that those persons living beyond the city possessed a peculiar immunity. However, the appearance approximately 2 months later in at least 6 Ohio River cities of an ailment which in all of its clinical manifestations corresponded with the Charleston cases makes it appear that the causative agent was contained in some vehicle which also was common to these latter cities, and further that this same vehicle was absent from the nearby cities of Norwood, Hamilton, Dayton, Columbus and Parkersburg. Immediately it is seen that any theory of an air-borne person to person route of infection becomes impossible.

Similarly milk and other foods are removed from suspicion. There remains but one possible avenue of communication which was common to all the inhabitants within any one individual affected city, at the same time common to all of the cities involved and not to those in which the outbreak failed to appear. This avenue of communication was the public water supply.

Charleston normally draws its water supply from the Elk River but for the period of the outbreak the water was largely from the Great Kanawha River. The Great Kanawha flows into the Ohio several miles above Huntington, W. Va. Aside from Charleston the only other cities known to have been involved in the outbreak use water from the Ohio, whereas cities located in the same general area but not using Ohio River water escaped. This even applied to Parkersburg, W. Va., which borders on the Ohio up-stream from the confluence with the Great Kanawha but which derives its drinking water from driven wells.

The natural assumption, therefore, is that the cause for this restricted epidemic was a bacterial infection of the gastrointestinal tract made possible by a let-down in the sanitary quality of the drinking water. However, there is no evidence to prove this.

Evidence as to the grossly polluted character of the waters of the Great Kanawha and the Ohio Rivers (Table I) need scarcely be given. The laboratory reports from each city show that the raw untreated waters were of their usual poor quality which from past experience are known to be capable of causing enteric diseases in the water drinking population, provided the safeguard of modern water purification is removed. No such break in the purification processes occurred at any time, as is shown by the *B. coli* indices of the treated effluent waters (Table II). The indices are without exception as favorable for the period of the outbreak as they have been for the corresponding months of other years. In addition this outbreak of acute gastroenteritis was not followed by an increase in the prevalence of typhoid fever, an occurrence which past experience has shown would surely follow the drinking of inadequately treated Ohio River water.

One of two groups of organisms is commonly associated with epidemics of gastroenteritis having an infectious etiology—(1) Infection with an organism of the bacillary dysentery group. This is commonly spread through the water supply. (2) Infection with one of the group

of organisms commonly associated with outbreaks of so-called food poisoning. These organisms are rarely if ever spread through the public water.

The outbreak which we have under consideration does not give the usually severe clinical picture of an infection with a bacillus of the dysentery group. The mild clinical manifestations more closely fit the clinical syndrome associated with food poisoning, but we are here confronted with the fact that the epidemic most surely was water-borne and appeared successively in at least 6 widely separated cities with a common water supply; whereas other neighboring cities with similar environments, except for the water supply, escaped.

Let us accept as a fact for the time being that the epidemic was a water-borne infection with one of the organisms mentioned. Then it becomes necessary to assume that this organism could appear in the public drinking water in sufficiently large numbers to cause such an explosive and widespread outbreak without there being a corresponding increase in the *B. coli* index; or we are forced to assume that these organisms are capable of resisting the various processes of modern water purification to an even greater extent than does the *B. coli* organism. Such reasoning does not seem plausible.

The circumstances at Charleston point even more strongly to a form of chemical gastrointestinal irritant than is the case in the other cities. The city water supply is normally drawn from the Elk River at a point in the Elk River Pool, $1\frac{1}{4}$ miles above the confluence with the Great Kanawha River. Due to the widespread absence of rain in 1930, flow in the Elk River gradually diminished until by late October it had practically ceased. Consequently there was a reversal of flow in the river below the water works intake so that the nearly stagnant water from the lower end of the pool and from the Great Kanawha entered the intake at the filter plant. This water was heavily charged with domestic sewage, soluble wastes from the city garbage dump, a variety of industrial wastes, the dissolved products from a heavy sludge layer on the bottom of the lower pool representing the sludge accumulation of years, and with a heavy growth of algae. Actual septic conditions prevailed in the Elk from the intake down to the Kanawha. This new water was entirely depleted of dissolved oxygen and showed *B. coli* present in 0.0001 c.c.

In spite of heroic water purification methods, which did succeed in producing an effluent free from turbidity and *B. coli*, the water received by the public still possessed the same nauseating odor and taste as was present in the raw water. The odor was similar to that escaping from an active septic tank. The taste was exceedingly offensive.

Both odor and taste were removed by boiling for a few minutes. The taste and odor became so disagreeable late in October and the first few days of November that the public practically refused to use the tap water for drinking purposes. The survey which the writer made on November 12 and 13 showed that in the families where sickness had occurred 80 per cent at the onset of illness were drinking the water as it came from the faucet, whereas in families where sickness had not occurred only 9 per cent stated they used such water, 41 per cent used boiled city water and the other 50 per cent obtained water from private sources. The fact that boiling the drinking water prevented the illness suggests that the cause might be a viable organism. However, the treated effluent consistently failed to show *B. coli* in five 10 c.c. portions, a fact which has always indicated a bacteriologically safe drinking water (Table III).

A series of events took place which may have some bearing on the outbreaks in the Ohio River cities. During the first week in November numerous dead fish appeared in the Great Kanawha opposite Charleston. Rain fell on the watershed of the Elk and Kanawha Rivers in December. Toward the end of December vast numbers of small fish died in the Kanawha, appearing particularly numerous 43 miles below Charleston. The dams on the Kanawha were lowered about January 1, the river having received enough run-off from the watershed to permit a good flush-out of the pools which had been accumulating wastes over a period of months. The men operating the dams complained particularly of the foul odors of decomposition coming from this released water with its accumulation of wastes. It is reported that numerous dead fish appeared in the Ohio River at Huntington and Ashland coincident with the appearance of illness in the inhabitants.

The prolonged absence of rain over the watershed of the Ohio and its tributaries caused a low water stage of unprecedented proportions. The dams were put in place on the Ohio early in May, 1930, and were still required at the time of the outbreak, thus establishing a series of pools into which only a small amount of diluent was added and in which there was only a sluggish flow. At the same time the volume of domestic and industrial wastes added to the river did not diminish. Because of the sluggish flow undoubtedly much of the undissolved wastes settled to the bottom, thereby building up sludge beds which under normal conditions would not have been possible. What new products of biological and chemical action were produced under such circumstances are unknown. Likewise the toxic action of sludge bed cleavage products has probably never before been tested on man on such a wide scale as took place at Charleston, and in a more dilute form in the Ohio River cities.

Tastes of a mild character do occur in the drinking water of all Ohio River cities from time to time, though never to such a degree as occurred in Charleston in early November. The presence of tastes and odors identical with those at Charleston, though less intense, appeared in the drinking water of each affected Ohio River city, being most intense during the period of the epidemic. This taste was not phenolic, but is better described as musty, decay-like, woody or mouldy. The odor from the hot water faucet was particularly musty. The taste at Louisville is described as distinctly strong and musty, which did not appear in the effluent water until the middle of January. This date coincides with the appearance of the illness in that city.

There is also a certain chronology in the appearance of the out-

break in each successive, down stream city. In Charleston it began about the last week in October and ended by November 10. Cases began in Huntington and Ashland on, or very near, January 1 and by the 10th a definite decline was taking place. Reports of cases in Cincinnati did not appear until about January 15 and it was not until after the 20th that the peak was reached. The peak at Louisville was apparently reached somewhat later than in Cincinnati.

Therefore, if we have correctly presented the epidemiological evidence in this series of outbreaks of gastroenteritis, the evidence is rather conclusive that the causative agent was transmitted by the public water supply which in the involved cities came from a common source. There is no epidemiological evidence to show that the ailment was produced by a viable organism contained in the water supply, unless we are to assume the sudden appearance of some bacterium or virus whose presence was not indicated by the established methods of water analysis. A series of stool cultures and serological examinations of many patients are also needed for a final answer.

The evidence strongly suggests that the acute gastrointestinal symptoms were brought about by the presence in the water of some chemical irritant whose physiological action simulated a strong purgative. The evidence does not show whether this chemical irritant was a cleavage product of bacterial action, a new chemical produced by bacterial synthesis, or the result of increased chemical concentration in the water brought about by a decrease in the diluent. There is at least a slight suggestion from the evidence that the toxic substance originated in the Great Kanawha River and was released into the Ohio when the dams were lowered on the Great Kanawha late in December, thereby releasing the pent-up wastes in a concentrated form which affected the public supply of each city as it moved down stream.

Raw or Pasteurized Milk

IN the extensive Lanarkshire milk experiment its authors concluded that "in so far as the conditions of this investigation are concerned, the effects of raw and pasteurized milk on growth in weight and height are, so far as we can judge, equal." The author of this article has rearranged the figures under the three groups 5, 6 and 7 yrs.; 8 and 9; 10 and 11, taking boys and girls separately, and produces tables which show a slight but distinct superiority on the basis of weight and height of raw over pasteurized milk. For all the children grouped together the advantage of raw milk for growth in weight is 0.86 ± 0.42 and for height 0.345 ± 0.006 . The actual differences are admittedly small, but the experiment only lasted for 4 months.—W. G. Savage, *Bull. Hyg.*, Aug., 1931, p. 639.

What a Public Health Nurse Expects of Her Chief—the Health Officer^{*}

AGNES J. MARTIN, R. N., F. A. P. H. A.

Director of Nurses, Bureau of Nursing, Department of Health, Syracuse, N. Y.

THE relationship between the health officer and the public health nurse is considered as that between an administrator and an executive. As a basis for discussion I have selected the functions for these two positions as outlined by Schell: ¹

The administrator determines policy. His major function is to represent equally the rights of the owners, the employees, and the public, a responsibility which has come more and more into his hands with the constantly rising status of management as a profession, and the waning influence of the board of directors as an administrative force in business operation. He guides and controls the progress of the enterprise in its fight for existence and advancement. He decides what shall be done and, in large measure, his success lies in the quality of business judgment shown in these decisions. He coördinates and keeps in proper balance all of the factors of the enterprise which are necessary to success. Having provided the agencies and paths of action, he delegates the action to others. He holds the executive responsible for the work itself.

An executive is one who is responsible for the execution of work performed by others. We look to him for accomplishment. We find him near the cutting edges of our industrial organizations where the main object is being approached. He is always close to the zone of action. Whether he be office manager in charge of clerks, district sales manager in charge of salesmen, or foreman in charge of workmen, his place is at the firing line. We may define the executive in still another way. He is the medium for the flow of orders and policies from the administrators to the employees.

The functions as outlined indicate definite fields, adequate preparation, and, I believe, mutual respect for each other's ability. The administrator has a slight advantage in that he has often selected the executive.

What then as public health nurses would we suggest to the health officer as standards for this selection? The National Organization for Public Health Nursing² presents minimum standards to succeed those

^{*} Read before the Health Officers Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 14, 1931.

offered at Boston in 1925 by the Nursing Section of the American Public Health Association and endorsed by the State and Provincial Health Officers, the Red Cross, and National Organization for Public Health Nursing. These standards in both instances were progressive for a period of 5 years and cover positions for staff nurse, supervisor and director.

I am sure we agree that education and experience are not enough, but they do make more effective the native ability of the individual. Pasteur said: "chance favors the mind prepared." Elimination of politics and improvement in the selection of personnel are the foundation of an efficient service. I cannot refrain from alluding to one of the replies to my request for advice on the content of this paper. It refers to the nurse applicant "who cannot forget her womanly charms long enough to get her work done. She is the person always recommended by a long list of gentlemen, often doctors, and sent to you with a letter from the man friend of Mr. Blank of the City Council—if no letter, he accompanies her personally and although 'only a friend' does all of her talking for her. You know her I'm sure." How well we all know her! A weakness for attractive women, however, is not limited to city fathers or health officers. A professor of home economics recently told me she had the greatest difficulty in placing her most capable but unattractive student because school superintendents preferred the pretty ones. I need hardly add that in a well organized service the executive nurse should have the privilege of recommending applicants, based on investigation and a personal interview.

What Does the Health Officer Expect of the Public Health Nurse?

To reduce the executive functions to practical public health organization—just what does a health officer expect of a public health nurse? First, I should say he expects her to execute the job, that is, to make possible expert nursing service in the one or more fields to which the service is committed. She is able to do this only when she has the authority to develop her program to conform to the best practices as outlined by such agencies as the National Organization for Public Health Nursing and American Public Health Association. Space permits only the mention of a few of the points they cover, such as procedures and technics, qualifications, supervision, staff education, salary, hours on duty, sick leave, and vacations.

The second thing a health officer should expect from the public health nurse is that he be kept informed on the service. Monthly reports of work performed are important, but they must be supplemented with thoughtful analysis and human interest. She, probably

more than any other person, has an opportunity to know the public's mind on the entire department program; yes, I might even say, to know what the medical profession thinks. She daily experiences the satisfaction of seeing the changing attitude toward confidence and respect for a modern health service, and too frequently hears the criticisms of the doctors because they do not know what it is all about. She should furnish opportune subject matter for education and publicity.

The third point might be included in the second, but for emphasis it has its place. Being close to the "firing line" she is able to observe community developments for new or coöperative services. In these days of reduced budgets there should be no duplication of work but a conscientious desire to carry on those services which officially belong to us. Dr. Ray Lyman Wilbur, Chairman of the White House Conference, in closing the second Conference, urged that all those present study the reports presented in relation to their own community needs and then make the application of the recommendations that fitted their situation.

Two instances of duplication in community service may be mentioned. In one, a preventorium maintained a field nurse to investigate applicants and follow up discharged cases. The official nurses were making regular visits in these same homes for infant, preschool, or school children, and in many instances had previously known the individual children. By transferring the field work to the official agency the preventorium was able to secure a much needed dietitian. In the other instance the city welfare department was sending an investigator into homes where a hospital order was requested by the prenatal clinic. This practice was discontinued when the nurse secured the data required for the records, which were practically those necessary to determine eligibility for clinic service.

Most men appreciate healthy, happy and contented women; so this is the fourth point a health officer expects. Probably no other time offers the same opportunity of selecting and maintaining a capable staff as the probationary period. This is the time to determine fitness for the job, for it is a difficult thing to eliminate the nurse unsuited to public health once she has received a permanent appointment. The consideration of the health of the staff is an important item—the nurse should exemplify the message she carries to the public. The things that make for a contented staff are a thorough introduction to the service with written policies or procedures for frequent reference, regular hours, a satisfactory salary, opportunity for promotion—in fact, those things which contribute toward a sense of fair

dealing and security in the job. I know a staff who although they failed to secure their automatic increases the past year willingly contributed a dollar a month per capita in addition to their annual pledge to the Community Chest during the winter months.

Every health officer sees his organization as a growing concern, which usually means increased personnel; this is especially true of the nursing service. He, therefore, looks to his directing nurse to recognize and develop those special abilities which make for leadership to meet a growing program. Staff education has come to be a recognized and legitimate expense of time and is compensated for in the interest and efficiency of the service rendered. Dr. Elliott Dunlap Smith of Yale has said: "Education is to create a thirst for knowledge, not to satisfy it—we must look on method as a growing thing which gives capacity to understand and reacts to enrich life." Public health nursing offers the most satisfactory laboratory experience. No two situations are alike, and the diversification of its application would indicate, through its growing demand, its success. These, then, represent what the writer believes a health officer expects of a public health nurse.

What Does a Public Health Nurse Expect of Her Chief, the Health Officer?

The first and most important factor is a definite, preferably written, purpose and policy of the organization service. Frequent changes are inevitable to meet the advancement in the growing field of public health. If the service is new and the budget is small, they should not be outlined to accomplish the millennium, so that the nurse is discouraged in attempting the impossible. Satisfaction in one's work is the best taskmaster. If too much is outlined the task is never completed.

Education of the community through publicity for a new project is an important step and saves endless explanations on the part of the nurse. This plan was most successfully carried out in Detroit in its Diphtheria Immunization Campaign last fall, before some 98 nurses were put in the field, and finally secured 73.3 per cent immunization of children between the ages of 6 months and 10 years.

The second point in importance is frequent opportunity for advice and discussion of developments, especially problems. In large departments with a full-time health officer and bureau chiefs, new projects are usually discussed in the commissioner's staff conference, giving the nursing executive an opportunity to register her opinion as to the feasibility of projects in relation to her field. Too often though, with

a part-time health officer, the program is outlined to the last detail without consulting the public health nurse on whom responsibility may fall for its execution. This, and a failure of his recognition before the nurses of the important part they play, and his acknowledgment of it before the rest of his department, dampen the enthusiasm and lower the morale of even the most capable staff. On the other hand, there are commissioners who never miss an opportunity to commend the staff as a whole, or individual members, when outstanding service is brought to their attention. Constructive criticism is equally welcomed when mistakes occur.

It is also important in a large organization that opportunity be offered by bureau chiefs for frequent conferences on procedure if the service involves clinic or field service supplied by part-time physicians followed up by public health nurses. Frequently the most skilled technic developed by a nursing service is entirely nullified by a hurried and indifferent part-time physician. I have seen the most carefully worked out technic for the administration of diphtheria immunization become a dangerous and confused procedure because a physician, arriving an hour late, was determined to jam his morning's work into the remaining time, and the entire protective measures built up by a conscientious nurse on a communicable disease case destroyed by a doctor sitting on the bed taking the temperature of a scarlet fever patient without cleansing his thermometer before or after using.

The third point has to do with the growth and development of the nursing service. We believe that nurses know and understand nurses, and that the method of approach to certain situations is to a degree intuitive. If, therefore, in complete understanding based on belief and respect for ability, the health officer permits experimentation in the development of a service, personnel, or what-not, he stimulates a unique and progressive service. This experimentation may involve such minor points as changing nurses' districts, rotating supervisors, change of hours, but maintaining the work day, etc.; or it may involve the entire program of the nursing service, as generalizing 2, 3 or any combination of services.

Public health nursing has arrived at its present stage of development through experimentation on the part of the private nursing agencies, but because of the difference in organization and administration we need experimentation in official organizations, such as that made possible in the 3 demonstration areas in New York through the Milbank Fund, and other notable demonstrations. It has been my privilege to have had a part in one of these developments and to have seen the interest and appreciation of a large number of American and

foreign visitors who observed the work. *Public Health Nursing* carries the "good news that the Commonwealth Fund has granted the National Organization for Public Health Nursing \$25,000 to finance a study of the present administration and practice of public health nursing. The study will cover both rural and urban services under official and unofficial administration in different sections of the country."

The fourth factor a public health nurse appreciates is an opportunity for advancement. Even resourceful people need recharging. The cheapest method is reading one's professional publications; the next, attending such meetings as this of the A. P. H. A., or other national health conventions, where one meets and hears leaders in the field. But to me the opportunity of the observation visit to an organization giving a good service in the field to be developed surpasses the chance discussion of a convention. The National Organization for Public Health Nursing is prepared to advise on where to observe outstanding work in the various fields of public health nursing.

Perhaps the most difficult method in official organizations for professional advancement, but the one which gives the greatest stimulation, is the leave of absence for study. Here you have all methods at your command, reading, hearing and meeting authorities in all fields, and contact with those of like purpose. I have had an interesting experience in observing the comparative value of the above opportunities, and believe there is a special value and even a proper sequence. A nurse who does not read her professional magazine has not much ambition or foundation to build on. However, with capacity to appreciate, the convention thrills and stimulates her to read more widely; the observation visit contributes new ideas, strengthens confidence in her own organization, and helps her to realize that all have problems; while study gives not only new knowledge and skill in her own field but opens up comparable fields and widens the chance of new and efficient application. These opportunities, however, are limited and should be given only to capable and ambitious nurses.

A continuous systematic and well planned staff educational program should be maintained to keep the entire staff in line with modern public health developments. In one community this program is planned by the directors of the visiting nurse, school, and health department services as a joint project for their three staffs. Much of the program the past year was presented by the county medical society. It has been estimated by various health authorities that one-third to one-half of the annual budget of the health department should be expended in nursing service. If this estimate is correct, the nursing

service deserves the same recognition as other services by making it a separate bureau headed by its own chief and operating with its own budget. Opportunity for approval by the executive nurse of all publications, publicity and questionnaires relating to the nursing service would also be appreciated, and in return any requests from her should be approved by the administrator.

One of the best means of securing interest in and recognition for a nursing service is through a lay advisory committee, well versed in the program. Volunteer service also offers opportunity for community understanding. The child welfare committee of a local Federation of Women's Clubs recently asked a department of health for the privilege of assisting in the child welfare clinic service. The request was gladly granted and 8 women, each representing a separate club, were instructed in their duties for clinic service. It would be hard to estimate the far reaching influence that these volunteers contribute to this particular service.

The sixth and last point deals with a personal quality and one that is hard to develop if it has not been a growing attitude. I refer to tolerance, "a recognition of the right of private judgment." Schell speaks of judgment as the "area of discretion." If this area is vague and the public health nurse is at a loss to know how far she may rightfully go, with a tolerant chief she will assist in defining the boundaries through the experiences of the work, for she must know her authority and responsibility to administer the service effectively.

I quote two valuable suggestions for coöperative participation in any field of endeavor: "Individually none of us is as good as he expects other people to be for whom he likes to set standards"; and "Acquire the habit of rating people not by the few things which attract or repel you, but by the general make-up, not just seeing people, but seeing into people."

NOTE: In order more completely to represent the public health nurse profession in the discussion of what she expects of her chief, the health officer, the writer solicited suggestions from official directors in various parts of the country. Gratitude is also expressed to the 7 health officers it has been her privilege to serve, who unwittingly have contributed to a long and varied experience.

Wyatt Galt Johnston*

THE American Public Health Association at the first meeting held in Montreal for 37 years deems it a privilege, through the authority of its President, Surgeon General Hugh S. Cumming, of the U. S. Public Health Service, and its Governing Council, to do honor to one of its most distinguished members who passed away all too soon.

Wyatt Galt Johnston, M.D., Professor of Hygiene at McGill University in 1902, was the son of a doctor in Sherbrooke, in the Province of Quebec. He received his early education at Bishop's College, Lennoxville, and subsequently was graduated from the Faculty of Medicine of McGill University in 1884.

As an undergraduate, his interest in pathology brought him into close association with Osler. Following upon his graduation, he worked under Virchow in Berlin, returning to Montreal to be appointed a demonstrator in pathology at McGill.

Later, at the Montreal General Hospital, he devoted himself to the subjects of pathology and bacteriology, and soon became actively interested in medico legal work. His command of these subjects was speedily recognized both by his university and by the bureau of health in the province. Not only was he appointed a lecturer in bacteriology at McGill University, but the Provincial Bureau of Health of Quebec named him as Bacteriologist, and he was made Coroner's Physician for the District of Montreal.

Within ten years of his graduation, he was a leading authority on the subject of medical jurisprudence and a pioneer in the teaching of this branch of work.

Few men of his time in Canada contributed so much and such valuable research in the field of public health. Among his more important contributions may be mentioned "A new method for the culture of diphtheria bacilli on hard-boiled eggs"—a practical method of rapid diagnosis for the determination of diphtheria. It was in this connection too that in 1892 he introduced the use of sterilized swabs in test tubes for the taking of cultures. Writing that year, Dr. Johnston spoke as a prophet when he condemned "the practice of withholding antitoxin until the diagnosis of diphtheria is clear," adding that

* Remarks at the Grave of Dr. Johnston by the Chairman of a Committee appointed by the President of the American Public Health Association, during the Sixtieth Annual Meeting at Montreal, September 14, 1931.

"probably a large proportion of the deaths from diphtheria arose from delay in the use of this remedy. One would think it better that the remedy should be given 99 times to persons not having diphtheria than to omit it in 1 genuine case." Surely the prompt giving of diphtheria antitoxin was never more strongly urged, and this too at a time when its value and harmlessness were still matters of doubt.

The value of the bacteriological diagnosis of leprosy received Dr. Johnston's attention, and he urged its practice.

A biological analysis of Montreal's water supply led him to recommend regular and frequent examinations, for which he devised a method of collecting water samples at various depths—a distinct and practical contribution to public health work.

Dr. Johnston's memory has a particularly happy connection with the American Public Health Association, for it was at the Buffalo meeting in 1896 that he presented his paper, "On the Application of the Serum Diagnosis of Typhoid Fever to the Requirements of Public Health Laboratories." His work was synchronous with that of Widal, although in the matter of priority of publication, Widal was the more fortunate. It was to Dr. Johnston, however, in these early years, that we were indebted for a very practical method of applying the Widal reaction for typhoid fever. In his communication, he says: "Instead of taking the serum as soon as it exuded, I allowed the drop to dry on pieces of paper, and found that, upon moistening it, subsequently, the solution obtained was just as efficacious as the pure serum for the purpose of the test." Its use became widespread and enabled the easy transmission, by post, from afar, of blood specimens to his laboratories, to the great satisfaction of rural practitioners.

When in 1902 (the year of his death) he became Professor of Hygiene at McGill University, he had attained the summit of his career as bacteriologist, pathologist, and expert on public health, while at the same time he was the accepted authority in the field of medical jurisprudence. To quote from Professor Welsh, "He was the outstanding authority in America," while as an original thinker his researches were conspicuous by their brilliancy and their integrity.

Most of all, Johnston is remembered by his contemporaries for his lovable disposition, his brilliant humor and his manly qualities.

This simple record of the man's life reflects, in some degree, his qualities and his character, but the lasting quality of his work and the survival of his personality depended still more upon the vision and nobility of character of the man himself. It was his rare nature that gave his life's work its peculiar significance, and this was appreciated even more deeply by the members of his profession and his many

friends. Love of truth, sincerity of purpose, and human understanding were among the guiding principles of his very existence.

A wreath furnished by the Association was then laid upon the tomb by Dr. C. L. Martin, Dean of the Medical Department of McGill University, an associate of Dr. Johnston.

The brief ceremonies were attended by Mrs. Johnston, her son, and a number of Dr. Johnston's old associates and friends.

Portugal Kindergarten in Children's Hospital

IN Lisbon, Portugal, one of the hospitals has had for some time a combination kindergarten-elementary school for children 3 to 10 years old confined to the hospital. Most of these children are suffering from protracted chronic diseases, such as tuberculosis of the bones or rickets; they are kept away from school for a long time, in some cases for years.

The school, which was established through the efforts of one of the physicians, is maintained by private contributions. The Government has accorded it the standing of a public school, and it is staffed by two teachers, who are normal school graduates.

In addition to suitable theoretical instruction, the children are taught manual work, singing, and drawing. The children participated in a recent international drawing contest. Motion pictures and other entertainments are also provided. It is reported that the children are much happier since the establishment of the school.—*Difesa Sociale*, Rome, May, 1931, p. 238.

ENNION GIFFORD WILLIAMS

1874-1931

COMMISSIONER OF HEALTH OF VIRGINIA, 1908-1931

A LIFE of devotion to the cause of public health ended with the passing of Ennion Williams on June 6, 1931. As a boy of 18 he had confessed a wish to devote himself to the nascent science of preventive medicine. A study period in Germany under Connheim and Pettenkofer fixed his determination. He taught bacteriology and preventive medicine while establishing himself in Richmond in the new specialty of roentgenology.

As a successful practitioner he entered public life for the sole purpose of securing a betterment in the health service of his city. At 34 he gave up his practice to become Virginia's first Commissioner of Health. For 23 years he lived and dreamed and worked and fought for the health of his state. He became more powerful than governors and bosses, because all knew that he wanted nothing for himself but everything for his work. He was a kind man, but he could be hard when his work needed it. He was a gentle man, but he could fight like a tiger when his work was attacked. He was a generous man, careless of his own means, but he grudged every penny that was not productive of better health. He worked too hard, he died too young; but he worked for a purpose and he achieved that purpose, and all Virginia mourned his passing.

THE HEALTH OFFICER OF SAN FRANCISCO

THE appointment of Jacob C. Geiger, M.D., by the San Francisco Board of Health and Mayor Angelo J. Rossi, as Health Officer for the City and County of San Francisco, to succeed the late William C. Hassler, M.D., is an event of more than usual importance from the standpoint of public health. The Mayor has followed the lead of Governor Pollard, of Virginia, and Governor Roosevelt, of New York State, in selecting a health officer on merit, regardless of political considerations.

Following Dr. Hassler's death, the Mayor sent a memorandum to the Board of Health stating that political affiliations and party lines should be laid aside in the search for a suitable successor. He pointed out that Dr. Hassler had served 31 years in the Health Department, 15 of which were as City Health Officer, and that his efforts had resulted in the development of a department of unusually high standards. He felt that the board owed it to Dr. Hassler's memory to let nothing interfere with the selection of the most competent man available. He also showed his recognition of the importance of public health work in putting fitness above political considerations.

The Mayor also suggested the appointment of an advisory committee consisting of the Deans of the University of California and Stanford Medical Schools, the President of the County Medical Society, the Chairman of the San Francisco Health Council, and others, to consult with the Board of Health in the selection of the best fitted candidate. After a careful study of all sides of the question and the qualifications presented by some 10 candidates, the committee unanimously recommended Dr. Geiger. The *San Francisco Chronicle* quotes Mayor Rossi as follows:

San Francisco is to be congratulated on the appointment of Dr. Geiger as Health Officer. I was deeply concerned in the selection of a man who would be a worthy successor of the late Dr. Hassler, who brought our Health Department to its present state of recognized efficiency.

In the selection of Dr. Geiger neither politics nor influence played any part. Guarding the health of our population is too serious a problem to admit of any criterion in the selection of a health officer other than outstanding and recognized ability in this highly specialized department of medical science.

Dr. Geiger is a native of Louisiana. He was graduated with the degree of Doctor of Medicine from the Medical Department of Tulane University in 1912. He was for 8 years Director of the Laboratory of the California State Board of Health, and for 5 years Executive Officer and Deputy Health Commissioner of Chicago. In addition to his degree of Doctor of Medicine, he holds the honorary degree of Doctor of

Public Health, which was conferred on him for important research on mosquito control. More recently he has been Professor of Epidemiology of the University of California Medical School and the George William Hooper Foundation for Medical Research. During the World War he served with the U. S. Public Health Service at Camp Pike, Ark., on mosquito control work. Later he became epidemiologist for the commission which studied botulism under the direction of Professor Jordan of the University of Chicago. In this work he traveled over a large part of the United States investigating many outbreaks of food poisoning. Dr. Geiger is epidemiologist to the Southern Pacific Railway and the Dollar Line of steamships. In this latter capacity, during the summer of 1931, he made a trip to the Orient for the purpose of studying ventilation on immigrant ships. It will be remembered that many cases of meningitis have occurred among immigrants on ships from the Orient, especially the Filipinos. The study was made particularly in view of this fact.

Dr. Geiger has had a wide and varied experience in public health work, and we can congratulate the City of San Francisco in obtaining the services of so competent a scientist as well as an executive. Let us hope that the enlightened action of Mayor Rossi will soon be the rule and not the exception, assuring communities of merit, and worthy officers of security of tenure.

ASSOCIATION NEWS

LOUIS I. DUBLIN, PH. D.

MEMBER OF THE AMERICAN PUBLIC HEALTH ASSOCIATION

LOUIS I. DUBLIN was born in Kovno, Lithuania, November 1, 1882, and was brought to this country in 1886. He was educated in the public schools of New York, and graduated from the College of the City of New York in 1901. Between 1901 and 1904, he was a graduate student in biology at Columbia University, receiving his doctor's degree in 1904. In 1907, he undertook for the New York City Department of Health a survey of the tuberculosis situation, reviewing existing facilities for clinical and sanatorium care. After some months of service in life insurance medical statistics, Dr. Dublin was invited to collaborate with the late Lee K. Frankel and Miles M. Dawson in the preparation of *Workingmen's Insurance in Europe*, a survey for the Russell Sage Foundation of insurance systems, and their health promotion auxiliaries, in Europe, published in 1909. During 1909 and 1910, Dr. Dublin also served as lecturer on actuarial mathematics at New York University. In 1911, he became Statistician of the Metropolitan Life Insurance Company, and since has specialized largely in vital statistics and closely related subjects having a direct bearing upon the life and health conservation function of life insurance institutions.

From 1917 to 1923, Dr. Dublin was visiting lecturer on vital statistics in the Department of Public Health at Yale Medical School. In 1918 and 1919 he served under Dr. William Charles White as Statistician to the Commission for Tuberculosis of the American Red Cross in Italy.

Dr. Dublin is the author of *Mortality Statistics of Insured Wage Earners and their Families* (1919); editor of *Popu-*

LOUIS I. DUBLIN, Ph.D.

lation Problems in the United States and Canada (1926); *Health and Wealth* (1928). He was also co-author of *The Money Value of Man* (1930) with Alfred J. Lotka, and with the late Lee K. Frankel, of *Principles of Life Insurance* (1911). He has published in proceedings of various learned associations, in magazines and the daily press numerous papers and addresses on subjects

in the public health and safety field, specifically on problems of racial and occupational mortality, infant and child mortality, cancer mortality, tuberculosis, the birth rate, population, sickness incidence and costs, etc.

During his 20 years of membership in the American Public Health Association, Dr. Dublin served for a time as Secretary of the Vital Statistics Section, and as Treasurer from 1925 to 1928 and again 1929-1931. He was President of the American Statistical Association, 1924; Chairman of the Statistics Section, National Safety Council, 1930; Secretary of the Section on Social and Economic Science, American Association for the

Advancement of Science, and a Vice President of that Association. At present he is Chairman of the American National Committee of the International Union for the Scientific Investigation of Population Problems, a member of the National Malaria Committee, the Medical Council Research Committee, United States Veterans Administration, and of Committees and Boards of Directors of many health and welfare organizations. In September, 1931, he was elected Third Vice President and Statistician of the Metropolitan Life Insurance Company, and at the Montreal meeting of the American Public Health Association, 1931, he was chosen President.

JOHN A. FERRELL, M. D.

PRESIDENT-ELECT OF THE AMERICAN PUBLIC HEALTH ASSOCIATION

DR. John A. Ferrell was born at Clinton, N. C., December 14, 1880. He was graduated from the University of North Carolina with the degree of B.S. in 1902 and with the degree of M.D. in 1907. For 3 years, from 1902 to 1905, he taught in the public schools and was county superintendent of schools in his native County of Sampson, N. C. After graduation in medicine, he did general practice for 2 years in a small town and was county health officer of Pender County, N. C. Through these two early experiences, as teacher and county superintendent of schools, and as general practitioner and county health officer, he acquired an appreciation of the fundamental relation of education to public health and gained an understanding sympathy for the interest of the rank and file of the medical profession that has contributed in no small way to his subsequent professional career.

Early in 1910, with the organization of the Rockefeller Sanitary Commission,

Dr. Ferrell was placed in charge of the Commission's work in North Carolina. For the next 3 years, 1910-1913, he directed an educational campaign against hookworm disease that resulted in the microscopic examination of 320,000 people, one-seventh of the population of the state, and in the treatment of 160,000 persons for the disease, that is, one-fourteenth of the population. So impressive was the conduct of the work in North Carolina for the eradication of hookworm disease that, with the transition of the Rockefeller Sanitary Commission into the International Health Board with its world-wide program, Dr. Ferrell was chosen as the Director for the United States.

Dr. Ferrell has contributed in a large way to the development of the basic policies that have characterized the work of the International Health Board, not only in its relation to the states of the Union, but in its relation to foreign countries. These basic policies, playing so important a part as they have in

the development of state and county health work in the United States, so completely reflect the mind of the Director of the International Health Board for the United States that they are mentioned here as reflecting the thought of the man whom the Association has honored with its high responsibilities. In general, the policies of the International Health Board are far-sighted, permanently constructive, and self-effacing; the agency itself never appearing in the foreground of the picture, indeed, rarely appearing at all. In particular, the International Health Board has followed consistently three guiding policies:

First, it has set up no new machinery through which to identify and perpetuate itself, but has always exerted its influence and made its contributions through the official, permanently constituted agencies of public health, the state and county health departments.

Second, the International Health Board has never undertaken work with the constituted authorities until after preliminary studies were sufficiently convincing to indicate that such work, once begun, would so appeal through its obvious merits to the constituency for whom it was done as to become, after a short period of time, self sustaining. The contributions of the International Health Board, therefore, have been predicated upon services so worth while that, if sustained through their initial development, would permit gradual withdrawal of the supporting agency and become established services.

Third, the International Health Board, with its world-wide viewpoint and experience, sharing the opinion of all authorities in the field of public health as to the most vital and essential need in the further progress of the movement, namely, adequately trained personnel, has during the last 15 years made large contributions for the establishment and maintenance of schools for

the training of public health officials, Dr. Ferrell himself being one of their first graduates, having received his

JOHN A. FERRELL, M.D.

Dr.P.H. from the Johns Hopkins School of Public Health in 1919.

Dr. Ferrell's contacts with the health officers of the United States have perhaps been, during his service of 21 years with the International Health Board, more extensive and more intimate than that of any public health official identified with the broad phases of the public health movement, and in all of these contacts his whole attitude has been one of broad understanding, genuine helpfulness and self effacement.

In his extensive contacts, Dr. Ferrell has very naturally been prominently identified with other organizations, having served as Chairman of the Public Health Section of the American Medical Association 1922-1923, as a member of the Council of the American Public Health Association 1926-1929, as

Chairman of the National Malaria Committee 1924, and as Secretary of the North Carolina Medical Society 1911-1913. He is author of numerous papers and booklets on public health service.

HEALTH DEPARTMENT REPORTS

AT the meeting of the Editorial Board of the *American Journal of Public Health* in Montreal, Professor Ira V. Hiscock suggested that it would be better for him in future to send his reviews of "Health Department and

other Reports" to Dr. Henry F. Vaughan to be incorporated in the section of Public Health Administration. It was decided to try this for the present; so readers may look for that material in the section noted.

All readers of the *Journal* are greatly indebted to Professor Hiscock for the very careful and excellent reviews which he has contributed for a number of years. The *Journal* takes this opportunity of expressing its appreciation of his services.

PUBLIC HEALTH ADMINISTRATION

Health in Syracuse—The staff of the Health Department numbered 172 in 1930, of whom 130 were full-time employees. The department is organized under 13 bureaus. The appropriation by the city was \$314,000 for health work or \$1.49 per capita. In addition to this, the Milbank Memorial Fund provided a grant of \$17,000 and paid for the services of 4 employees, while 7 others were paid by Syracuse University, and 3 by the Child Health Committee supported by the Community Chest. The death rate was 11.7 per 1,000 population, the lowest on record for this city.

Save for an outbreak of poliomyelitis with 150 cases, there were no abnormal conditions with regard to the communicable diseases. Diphtheria continued to decline, there being 23 cases compared to 31 in 1929, and only 2 deaths as compared with 4 for the preceding year. There were 4 cases of smallpox reported and there has not been a death for 42 years. The tuberculosis death rate has declined from 146 per 100,000 in 1908 to 47.7 in 1930, and 83 per cent of cases are now reported prior to death. There were known in the city 1,441 cases of tuberculosis. Of the fatal cases, nearly 40 per cent were reported more than a year prior to death.

Health education has received special emphasis in the Syracuse Health Department. During the year the newspapers were generous in the space given to health education, a total of 11,400 inches being given. The articles were illustrated with 101 pictures and there were 171 editorial comments. There were 51,600 copies of the monthly bulletin published, the mailing list being

4,000 per month. A regular weekly radio talk was broadcast. Application of the *Appraisal Form* gave a rating of 823 points. All divisions save venereal diseases, school hygiene, and preschool work rated 85 per cent or better.—George C. Ruhland, *Annual Report*, 1930.

Health in San Francisco—An appraisal has been made of the public health program for San Francisco for 1929–1930 by Professor Ira V. Hiscock. The government of the city and county combined is administered by a mayor and a board of 18 supervisors. The Board of Health consists of 7 members of whom 3 must be physicians. The term of office of each is 7 years. A full-time health officer is appointed under civil service regulations. The Board of Health, in addition to administering the health department, is responsible for the operation of the city hospitals, and the relief home. Plumbing inspection continues as a function of the health department.

In 1929 the personnel of the health department proper included 199 full-time and 28 part-time employees, of which number 72 were public health nurses and 49 inspectors.

The appropriation of the Board of Health for 1928–1929 was \$2,426,000, of which \$486,000, or \$.76 per capita, were used for public health services proper. The application of the *Appraisal Form* showed a score of 826 points which is one of the highest attained by any city thus far scored. Sixty-three per cent of this score is due directly to the efforts of the Board of Health, while 4 per cent is contributed

by the Board of Education, and 33 per cent by the voluntary agencies including the medical schools, clinics, Visiting Nurse Association, Tuberculosis Association, and child health agencies. Venereal disease control, tuberculosis control, infant and preschool hygiene, and popular health inspection scored less than 80 per cent.

Of the 7,968 deaths in the city in 1929, 282, or 3.5 per cent, occurred among the Chinese population, which represents 1.5 per cent of the total population, and 8.5 per cent of the tuberculosis deaths were among the Chinese. There is need of better analysis and graphic presentation of vital statistics. There should be a comprehensive program for a vigorous immunization campaign against diphtheria and scarlet fever.

The reporting of venereal diseases averages about half of what might be expected. There is need for more medical and nursing follow-up service. San Francisco has one of the lowest infant death rates of any American city. The mortality death rate has decreased from 75 per 1,000 births in 1915 to 49 in 1929. The infant mortality among the Chinese in 1929 was 71 as compared with the rate of 98 in 1921.

Clinic services have been extensively developed and are conducted along modern lines. There is need, however, of an increased nursing personnel for home visits on behalf of infants. The school health service is a joint function of the Board of Health and the Board of Education. Annual examinations are being made in the kindergarten, first and fifth grades, and parents are urged to be present.

Vigorous efforts should be made to secure an increase in the personnel of the nursing division and it is recommended that a generalized public health nursing district be established for experimental purposes.

The milk supply is obtained from 200 producing farms and 97.9 per cent of the supply is pasteurized. The per capita consumption is 0.63 pints per day. Most of the producing dairies are located within a radius of 40 miles of the city. The work of the Sanitary Bureau is well organized and scores 99 per cent.—Ira V. Hiscock, *Appraisal of Public Health in San Francisco*, Committee on Administrative Practice, A. P. H. A., 1931.

Health in Memphis—Under the supervision of Dr. W. F. Walker, a survey has been made of health problems and facilities in Memphis and Shelby County, Tenn. In 1929, the staff of the department included 87 full-time and 14 part-time employees, in contrast to 49 full-time and 6 part-time employees in 1919. The total expenditures for public health activities in 1929 amounted to \$152,776.83 or \$.79 per capita, of which sum \$.28 were spent for public health nursing. Of the taxpayers' dollar, \$.02 were spent for health work.

Application of the *Appraisal Form* gave a weighted score of 619 points, the principal weakness being in the divisions of Infant, Preschool, and School Hygiene and popular health instruction, each of which rated less than 50 per cent of the standard.

The total death rate including resident and nonresident was 20.1 per 1,000 in 1929, being 15.7 for the white population and 29.0 for the colored. Excluding the nonresident deaths, the rate was 15.7 for the total population, 10.5 for the white population, and 26.2 for the colored. One factor which contributes to the high death rate is that Memphis is a hospital center for the surrounding area, 21.8 of all deaths having been among nonresidents. This is high when compared with the average American city. The death rate from tuberculosis

of all forms was 176.1 per 100,000, the rate being 70.1 for the white, and 387.2 for the colored. There is need for the execution of a plan to transfer to private physicians the responsibility for diphtheria immunization and medical examinations of preschool and school children.

A large number of births occurred in hospitals, 55 per cent of total births, 67 per cent for the white and 38 per cent for the colored. The maternity service attained the high score of 93 per cent; a total of 1,816, or 46 per cent, of all the births which occurred in 1929 were registered at the prenatal clinic of the Health Department. The work of the Sanitary Bureau is well organized, there being a special effort to secure installation of sewer connections in parts of the city which have previously been unserved.

Malaria control work has been en-

gaged in with extensive ditching and drainage to eliminate mosquito breeding places. There were 214 cases of malaria reported between June 15 and Oct. 1, and a special effort was made to popularize education in malaria prevention. The public health nursing division has made noteworthy progress although there is need for an increase in the nursing staff. The major change in organization recommended is the administration of all activities relating to tuberculosis control through a division of tuberculosis. It is also recommended that the departmental staff be increased to 119 full-time and 21 part-time employees, and that the yearly appropriation for 1930 be increased to \$205,091. —*Survey of Health Problems and Facilities in Memphis and Shelby Counties, Tennessee, for 1929*, Shelby County Tuberculosis Society, Memphis.

LABORATORY

A STUDY OF THE EIJKMAN METHOD FOR DETECTION OF FECAL CONTAMINATION OF WATER*

GEREON M. S. WAGNER

University of Pennsylvania, Philadelphia, Pa.

EIJKMAN¹ attempted to simplify the method for detecting colon bacilli in water by taking advantage of the fact that fecal strains can be grown at 46° C. He incubated inoculated lactose broth fermentation tubes at this temperature and interpreted the results

on the basis of gas formation. Brown and Skinner² found that only a small percentage of colon bacilli isolated from human feces produced gas in 24 hours at 46° C., and that 48 hours were necessary to include all gas-formers. They also found that many "typical" colon bacilli from polluted streams failed to grow in the Eijkman broth at 46° C. and that the test did not entirely eliminate *B. aerogenes*.

* This paper is abstracted from a thesis prepared in partial fulfillment of the requirements for the degree of Master of Science in the Graduate School of the University of Pennsylvania.

In order to test the value of the Eijkman method of detecting colon bacilli in water the following studies were carried out.

One hundred and sixty colon-like organisms from various sources were fished in duplicate from Endo plates—82 were from Endo plates inoculated with samples of human feces from 82 different persons, 3 were from plates inoculated with urine, and 75 came from as many different samples of water. All the cultures from the Endo plates were inoculated into lactose broth in duplicate. One culture was inoculated at 37° C. and the other at 46° C. for 48 hours.

Each strain was studied to determine its morphology, motility, and Gram staining reaction; its ability to liquefy gelatin, to produce indol, to form acetyl-methyl-carbinol, to grow in citrate solution; and to test its power to ferment sucrose and lactose broth. Three species were isolated—*B. coli communis*, *B. coli communior*, and *B. aerogenes*. These were divided in three groups. Group I included the organisms that gave acid and gas in lactose broth at 37° C. and at 46° C.; Group II included those that showed acid and gas at 37° C. but neither acid nor gas at 46° C.; Group III comprised the strains that gave acid and gas at 37° C. but only acid at 46° C.

Of the strains from human feces classified in Group I, 36 were *B. coli*

communis, 22 *B. coli communior*, and 2 were *B. aerogenes*. In Group II, 2 were *B. coli communis*, 3 *B. coli communior*, and 2 were *B. aerogenes*. In Group III, 6 were *B. coli communis*, 8 *B. coli communior* and 1 *B. aerogenes*.

Of the strains from urine in Group I, 1 was *B. coli communis* and 1 *B. coli communior*. In Group II, 1 was *B. coli communior*.

Of the strains from water in Group I, 19 were *B. coli communis*, 17 *B. coli communior* and 10 were *B. aerogenes*. In Group II, 2 were *B. coli communis*, 6 *B. coli communior* and 2 were *B. aerogenes*. In Group III, 7 were *B. coli communis*, 5 *B. coli communior*, and 7 were *B. aerogenes*.

It is concluded that the Eijkman test is not trustworthy because of the great variation in the results obtained. Even though many cultures of the three species studied produced acid and gas in lactose broth at both 37° C. and 46° C., the percentage of gas was, on an average, lower at the higher temperature. Many otherwise typical strains of *B. coli communis*, *B. coli communior*, and *B. aerogenes* produced no gas but only acid at 46° C. or neither acid nor gas at this temperature although they fermented lactose at 37° C. with the formation of both acid and gas.

SIMPLE TEST FOR AVAILABLE CHLORINE STRENGTH OF DAKIN'S AND OTHER SODIUM HYPOCHLORITE SOLUTIONS OF EQUIVALENT STRENGTH

A. H. ULLRICH

Director of the City Laboratory, Fort Smith, Ark.

WHILE both the arsenious acid-iodine-starch titrimetric method and the dilution-orthotolidin colori-

metric method for the determination of available chlorine in hypochlorite solutions seem simple enough in the hands

of a chemist or skilled technician, these methods are apparently too difficult to find general application in the routine work as carried out in the great majority of hospitals. Realizing the need for a rather simple test whereby a comparatively unskilled helper can at intervals check the strength of Dakin's and other equivalent chlorine solutions, we have devised a modification of the above mentioned procedures.

PRINCIPLE

In the proposed method the percentage of available chlorine in Dakin's and other equivalent hypochlorite solutions is taken arbitrarily to lie between 0.45 and 0.55 per cent (For practical purposes these limits are close enough to the U. S. P. limits of 0.45 and 0.50 per cent for the modified Dakin's solution). With this as a basis, the quantity of standard tenth normal arsenious acid solution necessary to neutralize exactly a definite fixed quantity of chlorine solution is calculated for each of these limiting strengths. Thus by adding these calculated quantities of standard arsenious acid solution to two separate but fixed and equal quantities of Dakin's solution there is complete neutralization of the chlorine in one, and only partial neutralization in the other. The completely neutralized solution will show no color change on the addition of orthotolidin, while the partially neutralized solution will show a yellow or even orange color, depending on whether the particular solution in question approximates 0.55 or 0.45 per cent of available chlorine.

APPARATUS

Pipette graduated to deliver 5 c.c. Dakin's or equivalent chlorine solution. (Note: Our test is based on the use of a 5 c.c. sample of the solution to be tested.)

Pipette with two graduations, the first to deliver 6.43 c.c. N/10 As_2O_3 , the other to deliver 7.86 c.c. N/10 As_2O_3 .

Two 2-oz. ground glass stoppered bottles to be marked No. 1 and No. 2 respectively for convenience.

1 c.c. medicine dropper for orthotolidin.

Reagents

Standardized N/10 As_2O_3 solution.

Standard orthotolidin solution.

PROCEDURE

To each of the 2-oz. bottles add approximately 20 c.c. of distilled water and then exactly 5 c.c. of the solution to be tested.

To bottle No. 1 add standard arsenious acid solution as measured by the lower mark on the graduated pipette or 6.43 c.c.

To bottle No. 2 add standard arsenious acid solution as measured by the upper mark on the graduated pipette or 7.86 c.c.

Shake contents of both bottles.

Add 1 c.c. orthotolidin solution to each bottle.

RESULTS

No color in either bottle—solution tested weaker than the accepted Dakin's solution.

Yellow to orange color in bottle No. 1 but no color in bottle No. 2—solution tested has correct strength for accepted Dakin's solution.

Color in both bottles—solution tested is stronger than accepted Dakin's solution.

With the aid of this test previously prepared solutions can be adjusted to the Dakin's strength by either strengthening or diluting them as the case may be. Where both bottles show color the depth of color can be used as a guide in determining further dilution.

This procedure is not applicable for testing solutions containing oxidizing agents other than chlorine. It is intended only for solutions of chlorine or hypochlorites in which available chlorine is between 0.45 and 0.55 per cent.

VITAL STATISTICS

Census of Scotland, 1931—The population of Scotland on April 26, 1931, was 4,842,554, of whom 2,325,867 were males and 2,516,687 females. At the census of 1921 the total population was 4,882,497—2,347,642 males and 2,534,855 females. The 1931 population is thus 39,943 less than that reported at the 1921 census, the decrease of males being 21,775 and that of females 18,168. The intercensal decrease of the total population is equivalent to 0.8 per cent of the 1921 population, that of males being 0.9 per cent of the male population in 1921, and that of females 0.7 per cent of the female population in 1921. The number of females in the population exceeds that of males by 190,820. This excess of females over males is only 3,607 more than at the census of 1921, but is greater than at all previous censuses—the maximum difference previously being that of 1921, viz., 187,213. The ratio of females to males which was 108.0 to 100 in 1921 is now 108.2 to 100, though this ratio is not itself a maximum.

This is the first official census of Scotland which records a decrease of population. The first census was taken in 1801, when the population was reported to be 1,608,420, and each successive decennial census showed an increase, culminating in a total population of 4,882,497 at the census of 1921. The largest of these increases was one of 446,456 at the census of 1901. In 1911, the increase fell to 288,801 and in 1921 to 121,593. The natural increase of population in Scotland, i.e., the excess of births over deaths, during the intercensal period, amounted to 352,386, and as a decrease of 39,943

was found in the population, 392,329 may be taken as a measure of the population lost by migration. The natural increase in 1921–1931 was smaller than in any intercensal period since 1871.

The decrease of population in Scotland at the present census has been general in the counties. Only 6 out of the 33 counties (inclusive of burghs) show an intercensal increase, the 2 most noteworthy being increases of 2.2 per cent in the case of Lanark and 3.9 per cent in Midlothian. Decreases are recorded in 27 counties, amounting to 8.4 per cent in Orkney, 9.3 in Caithness, 9.6 in Sutherland, 11.3 in Ross and Cromarty, and 16.1 in Zetland. The counties of Argyll and Bute show the much greater decreases of 18.0 and 44.2 per cent, respectively, but both of these counties were materially affected by the taking of the 1921 census in the holiday month of June—the populations then returned being altogether abnormal and not admitting of comparison with the results of the present census. The same consideration to a less extent affected the holiday areas of other counties, e.g., Ayr and Fife. Even at the recent census the presence of visitors in appreciable numbers has been noted in the returns of certain holiday resorts.

Of the total population of Scotland 38.6 per cent are embraced in the four chief cities of Edinburgh, Glasgow, Dundee and Aberdeen, 15.7 per cent in the remainder of the 24 larger burghs as defined by the local government (Scotland) act, 1929, and 15.1 per cent in the small burghs, giving a burghal population of 3,361,384 or 69.4 per cent of the entire population, against 3,334,499 or 68.3 per cent at the census of 1921—an increase of 0.8 per cent. Of

the 24 large burghs 15 show an increase of population over that of 1921. The largest increases recorded are 36,890 in Glasgow, 18,734 in Edinburgh, 8,296 in Aberdeen and 7,268 in Dundee. The largest percentage increases are 7.8 in Inverness, 6.2 in Falkirk, 5.9 in Kilmarnock and 5.8 in Stirling. The largest decreases recorded are 4,945 in Dunfermline, 4,161 in Motherwell and Wishaw, 2,185 in Greenock, and 1,859 in Arbroath. The largest percentage decreases are 12.4 in Dunfermline, 9.5 in Arbroath, 6.9 in Port-Glasgow, and 6.0 in Motherwell and Wishaw and in Dumbarton. The abnormal decrease in Dunfermline is doubtless due to some extent to changed conditions at Rosyth. Some portion of the apparent increase shown in the large burghs may be ascribed to the absence of persons on holiday at the date of the 1921 census.

It is, however, the county areas outside the large burghs that have contributed most to the decrease in the total population. The population of the small burghs has declined from 769,245 in 1921 to 730,221 in 1931, a loss of 39,024 or 5.1 per cent, and that of the landward portions of the counties has fallen from 1,547,998 in 1921 to 1,481,170 in 1931—a decrease of 66,828 or 4.3 per cent. Thus while the population of the burghal area of Scotland has increased by 0.8 per cent, that of the landward area has decreased by 4.3 per cent. In the period 1911 to 1921 the rates of increase for the 2 areas were almost identical, being 2.6 per cent for the burghal area and 2.4 per cent for the landward.

In only 4 of the 33 Scottish counties are landward increases recorded in 1931, 6.5 per cent in Renfrew, 3.1 per cent in East Lothian, 1.1 per cent in Lanark, and 0.1 per cent in Midlothian. Elsewhere in the landward areas the decrease was general, the principal percentage decreases being 9.5 in Orkney, 9.7 in Sutherland, 9.8 in Kincardine,

11.5 in Caithness, 12.0 in Ross and Cromarty, and 17.1 in Zetland. Decreases of 14.5 per cent in the landward of Argyll and of 41.6 per cent in the landward of Bute are, as already explained, largely due to the presence of holiday populations in 1921. It will be observed that the increases and the smaller decreases are generally in those counties in which the landward areas are to some extent of an urban or semi-urban character, and that the larger decreases are in those counties, chiefly in the North and North-West, which are more rural in character.—*Prelim. Rep. Fourteenth Census of Scotland, 1931, p. 6-7.*

Abortion and Birth-Rate in Hungary—The number of abortions in Hungary has more than doubled in the last 20 years; at the same time the birth rate has fallen from 40.5 to 24.7 per 1,000. The number of abortions amounts to between 110,000 and 120,000 every year, and of these 70 per cent are criminal abortions. The cause of this state of affairs is attributed to the lax standards of doctors as to indications for induced abortions.

According to Hungarian law, pregnancy may be interrupted only if the life of the mother is earnestly menaced by pregnancy as such. The actual text of the law does not recognize even this indication, although legal practice has countenanced it. According to prominent Hungarian gynecologists, the law should be revised and reworded.

According to a recent lecture by Dr. Fekete, lecturer to the University of Budapest, it is generally held in Hungary that to allow artificial abortion without restriction would be equivalent to national suicide. In Soviet Russia artificial abortion was declared permissible in 1920, but only in institutions, and this has not proved an ideal method of dealing with the problems.

The public is not wholly aware of the

dangers of abortion; the mortality amounts to 1.2-3 per cent, and morbidity follows in 14 per cent of the cases, even if the operation is performed in well-equipped, modern operating theatres. In Hungary more than 1,200 women succumb to artificial abortion every year, and 6,000 to 8,000 women have ill-health following the operation.

The loss of population due to abortion ought at least to be compensated for by the increased care and protection given to mothers and infants but in Hungary the proportion of maternity beds to births is 990 to 200,000. In some places the ambulance has to carry a woman in labor a distance of 35 to 70 miles.—*Lancet*, 2: 314 (Aug. 8), 1931.

Vital Statistics for New Zealand, for the Year ended March 31, 1931—The mean population of the Dominion of New Zealand (exclusive of Maoris) for 1930 was estimated to be 1,425,084. This represents an increase over the corresponding figure for the previous year of 18,142, or a percentage increase of population of 1.29. The births of 26,797 living children were registered during 1930 as against 26,747 in 1929, bringing the birth rate for 1930 down to 18.80 as compared with 19.01 in 1929, 19.56 in 1928, 20.29 in 1927, and 21.05 in 1926. With 12,199 deaths and 26,797 births, the excess of births over deaths was 14,598 persons, or a natural increase of 1.0 per cent only of the total population. In 1870 the natural increase was 3.1 per cent.

There were 12,199 deaths in 1930 as compared with 12,314 in 1929, lowering the death rate from 8.75 in 1929 to 8.56 in 1930. Heart disease (all forms), apoplexy, or cerebral hemorrhage, and diseases of the arteries, combined, accounted for 3,988 or 32 per cent of the total deaths in New Zealand in 1930. In 1929, these diseases accounted for 29 per cent, and in 1928 for 28 per cent of the total deaths. Cancer has shown

an increase during the last 5 years. In 1926 the death rate from this disease was 99.1 per 100,000 as compared with 101.9 in 1930. The 1,452 cancer deaths in 1930 comprised 11.90 per cent of the total deaths from all causes. New Zealand has the lowest death rate from tuberculosis in the world. In 1930, the lowest rate (45.5 per 100,000 population) in the last 5 years was reached, but even so, tuberculosis still took fifth place as a cause of death in New Zealand.

Among the common infectious diseases, pneumonic influenza, diphtheria, typhoid fever, and scarlet fever all showed decreases within the last year. The death rates per 100,000 population for 1929 and 1930 respectively were: pneumonic influenza, 8.5 and 4.6; diphtheria, 6.5 and 4.1; typhoid fever, 1.6 and 0.5; and scarlet fever, 1.9 and 1.1. Neither whooping cough nor measles is compulsorily notifiable in New Zealand.

There was a slight increase in the infant mortality in 1930, when the death rate of infants under 1 year of age was 34.48 per 1,000 live births as compared with the 1929 rate of 34.10. The reduction in infant mortality in the last five years, however, has been considerable—from 39.76 in 1926 to 34.48 in 1930.—*Report of the Director-General of Health, New Zealand, for the Year ended Mar. 31, 1931*, p. 5-9.

Vital Statistics for Illinois, 1930—Since reliable statistics have been kept, the State of Illinois has never experienced as low a birth rate as the one reached in 1930. There were 128,121 births recorded, giving a birth rate of 16.7 per 1,000 population. The excess of births over deaths was 44,529 and the difference between the birth and death rates was 5.8 per 1,000 people, indicating a net increase in the population from reproductive sources of 0.6 per cent. Experience in the past indicates that from 1,000 to 2,000 delayed birth re-

ports will be filed during 1931 and from 100 to 200 death certificates. These additions will make no significant difference in the rates, however.

The general death rate in 1930 was 10.9 per 1,000 population. Never before since the state was admitted to the death registration area in 1918 has the death rate been so low. The best previous record was in 1921 when the rate was 11.1. The total number of deaths from all causes in 1930 was 83,592.

The number of deaths from typhoid fever in Illinois went up from 110 in 1929 to 154 in 1930, causing an increase in death rate per 100,000 population from 1.4 in 1929 to 2.0 in 1930. Prior to 1900 most of the typhoid fever occurred in the cities. Now most of it occurs in the small towns and rural communities. In 1930, for example, the death rate from typhoid in Illinois cities of more than 10,000 population was 1.4 per 100,000 people while the rate in the remainder of the state was 3.0. The urban rate would have been still lower if no fatal cases from rural districts had obtained hospital care in the cities. Typhoid fever has become a problem chiefly of the southern third and the rural parts of the state.

The year 1930 marked a new low level for tuberculosis. Deaths from this disease numbered only 4,790 against 5,244 in 1929, giving death rates of 62.5 and 70.0 for 1930 and 1929 respectively. In no previous year since 1886 when the population was only half its present number had less than 5,000 deaths from tuberculosis been recorded in Illinois. There were 545 fatalities from diphtheria, giving a death rate of 7.1. Of these deaths, 411 occurred in Chicago, and 134 down-state, making the death rate for Chicago 12.1 and that for the remainder of the state 3.2. Excepting in 1927 when 102 deaths occurred, infantile paralysis mortality was heavier in 1930 than in any year since 1921. There were sixty deaths, giving

a death rate of 1.2 from this cause in 1930. The scarlet fever death rate of 4.0 per 100,000 population is identical with the rate for 1929. Though the prevalence of this disease was high in both years the fatality was low, averaging less than 2 deaths per 100 cases. Pneumonia was responsible for 5,272 deaths in 1930; the death rate of 68.8 is lower than the lowest previous rate (78.8), which was recorded in 1921. Measles caused 90 deaths, giving a death rate of 1.2, which rate was second only to the rate of 1.1 which was attained in 1928.—*Illinois Health Quarterly*, 3: 152-159 (Apr.-June), 1931.

Analysis of the Census of 1926 for the Irish Free State, According to Ages, Orphanhood and Conjugal Conditions—According to a preliminary analysis (by ages, orphanhood and conjugal conditions) of the statistics contained in the 1926 census of the population of the Irish Free State, the proportion of persons unmarried in the Saorstát at each age is much higher than in any other country and marriages take place here at a comparatively late age. This applies both to males and females. At age 35-40, there are, in proportion to the population, three times as many unmarried males as in either Denmark or England and Wales. Of the females, 62 per cent are unmarried at the age of 25-30, whereas in the United States only 23 per cent are unmarried at that age. Moreover, this situation is steadily growing worse year by year. In 1841, 15 per cent of both males and females, at age 35-45, were single but in 1926 the number of single males at that age had increased to 45 per cent and single females to 29 per cent.

More males are unmarried at every age in the rural areas than in the towns. With respect to the females, however, this is true only of the early ages; above 35, a larger percentage of the females

are unmarried in the towns than in the rural areas.

The Saorstat has few married women of child bearing age. In proportion to the population there are only half as many married women under 45 years of age as are in the United States; only about 61 per cent of the number in England and Wales and about 66 per cent of that in Denmark.

Nevertheless, the married women of the Saorstat rear far more children than those in other civilized countries. In 1926, there were 131 children under 5 years per 100 married women under age 45, compared with 77 in the United States, 75 in Germany and 71 in England and Wales. Furthermore, this rate has not been declining as in other countries; in 1861 it was 130 as compared with 131 in 1926. In England and Wales, on the contrary, it decreased from 116 in 1861 to 71 in 1926.

Owing to the late marriages, the average age of Irish Free State mothers is much higher than in other countries. If the average age of married women in other countries were the same as in the Saorstat the difference in fertility would be even more marked. On this basis, the Irish mother raises more than twice as many children as the American mother and almost twice as many as a

married woman in England and Wales. The general birth rate, however, is kept down as a result of the shortened child-bearing period caused by the late marriages.

Another result of the advanced age at marriage is the high death rate of parents of young children. Consequently, a larger proportion of orphans under 15 years of age are to be found in the Saorstat than is usual in other countries.

The lateness of marriage of males and the low death rate of elderly females result in a comparatively large number of widows, although marriages here are proportionately fewer than in other countries. In 1926, 41 per cent of the widows were over 70 years of age.

The Irish Free State has the largest number of persons over 65 years of age per 100 persons 15 to 65 of any other important civilized country. In 1926, the rate was 14.8 compared with 7.4 in the United States, 9.1 in England and Wales and 8.4 in Germany.

The expectation of life of males at birth in 1926 was 57.4 years but at age 70 it was 10 years; for females, at birth, it was 57.9 and at age 70, 10.7. As in other civilized countries the expectation of life has been increasing in recent years.—*Census of Population, 1926. Saorstat Eireann*, pp. 1-33.

PUBLIC HEALTH ENGINEERING

TRAINING FOR THE PUBLIC HEALTH ENGINEER*

DISCUSSION

EARLE B. PHELPS

*Professor of Sanitary Science, College of Physicians and Surgeons,
Columbia University, New York, N. Y.*

PROFESSOR Prescott has very clearly set apart the profession of public health engineering from that older branch of the engineering school with which it is even today so commonly confused, namely, sanitary engineering. This difference, as he has indicated and which the writer would re-state because of its importance, is largely one of emphasis. The sanitary engineer is primarily a designer or a builder. He is, in fact, a civil and hydraulic engineer specializing in a rather restricted field, confined for the most part to works relating to municipal water supply and sewerage.

The public health engineer on the other hand is primarily a student and worker in the field of public health. The range of his activities is wider, and his training and knowledge are of essentially different character. It is not so important that he know how to build a sewer as that he know why sewers are necessary and what results may be anticipated from the discharge of their contents without treatment into a body of water. Trained to think with the clearness and accuracy of an engineer, he employs as his material the data of physics, chemistry, and biology which

underlie the present-day practice of public health.

Working with the physician or the physiologist he may make important contributions in such fields as school hygiene, or industrial hygiene, when the problems are largely physiological or pathological. The writer assumes that Professor Prescott's inclusion of industrial hygiene and health hazards in industry, within the scope of public health engineering, refers to the environmental aspects of these problems and not at all to their purely medical aspects.

Professor Prescott has indicated in some detail the content of a 4-year undergraduate course at the Massachusetts Institute of Technology leading to the degree of Bachelor of Science in Public Health Engineering. It may be of interest, therefore, to refer in comparison to the postgraduate course offered at the DeLamar Institute of Public Health, College of Physicians and Surgeons, Columbia University, in which we attempt to accomplish essentially the same object in a distinctly different manner.

This course is based upon the reasoning employed above in defining the public health engineer. It is a course of 1 full year, of 12 months, open to acceptable graduates in civil engineering and leading to a degree of Master of Science in Public Health Engineering. It presupposes adequate engineering training

* Discussion of paper by S. C. Prescott, read before the Public Health Engineering Section of the A. P. H. A., at the Sixtieth Annual Meeting at Montreal, Canada, September 17, 1931 (see October JOURNAL, page 1091).

and attempts to provide the supplementary public health background necessary to direct the young engineer's activities into channels which are essentially new to him and which lead him to consider the relationships between the environment and human health. Among the prerequisites therefore are adequate courses in physics, chemistry and either general biology or bacteriology. Since these last two subjects are generally weak and sometimes lacking in engineering education, the candidate may be required to complete certain work in the summer school previous to entering upon his year's study, and in any event the laboratory work has to be begun in a more elementary manner than is usual in graduate studies.

We have the distinct advantage, however, of having the candidate strictly within a small department for most of his time, which permits of intensive courses and close correlation between courses. We believe it also to be an advantage, rather than otherwise, that the student has completed his formal engineering studies so that the entire time and attention of a somewhat more mature student can be devoted to systematic training in public health.

The major work of this course is given under the titles "Public Health Engineering" and "Public Health Engineering Practice." In the first of these the subject is dealt with along the lines of the writer's textbook, *Principles of Public Health Engineering*, namely, the three major environmental contacts—air, water, and food—and certain other miscellaneous environmental factors. Under air we study both ventilation and atmospheric pollution by cities and by industries; and under water, both water supply and sewerage, which we purposely link together as complementary; and under food we treat two examples, the pasteurization of milk and the sanitary control of the collection and marketing of shellfish.

Among the matters of secondary importance considered are illumination, municipal cleansing and refuse disposal, and insect and rodent control. In each of these topics the stress is upon the fundamental chemical, physical, bacteriological, physiological or biological data upon which the engineering practice rests, and each topic therefore provides in its turn a basis for the construction of a considerable educational edifice of public health material.

Public Health Engineering Practice is an advanced course in which a special problem of some magnitude is developed by each student in a comprehensive manner.

The other foundation courses are vital statistics in which the material dealt with is directly related to public health, epidemiology with special stressing of the environmental factors, and sanitary engineering laboratory methods in which, as previously indicated, the student generally starts at the beginning and learns enough of chemical and bacteriological technic to complete a satisfactory examination of air, water, milk, or shellfish, and to understand and interpret the results of such examinations as well as those of the more strictly medical tests of blood, urine, throat cultures, etc.

These classroom courses are all of seminar nature, made possible by small groups of students, and are accompanied by extensive collateral reading and frequent reports by the student. Finally there is required during the summer a so-called field study in which the candidate is assigned to some definite organization, such as a state department of health, and is allowed to select a specific topic for survey or investigation under the actual conditions of practical administrative work. He is also required to take, either in connection with his field work or during the year, one optional study closely related to his selected field study and these together

provide the basis for his graduating thesis which completes the requirements for the degree.

The course outlined here parallels another course designed primarily for graduates in medicine or for students having had at least a full pre-medical college course and who likewise take the first general course in public health engineering. The objective here, however, is to provide a background for the proper interpretation of their future work in epidemiology and public health administration. The seminar method of teaching permits of considerable latitude in the assignment of problems and topics

for discussion and each of the two groups of students admirably supplements the other's viewpoint, to their mutual advantage.

In this way we recognize what we believe to be an essential distinction in public health activities, namely, the medical and the engineering aspects. In either case we have found it distinctly advantageous that the doctor of medicine or the civil engineer, as the case may be, has come to the decision to enter the profession of public health as a specialty and comes to us well prepared and with a definite objective as to his future career.

The Use of Activated Carbon in Removing Objectionable Taste and Odors—The author suggests the use of the terms "carbon adsorption beds" and "carbon units" rather than "carbon filters." Experiments have been conducted in units of two sizes, one a bed 3.56' in diameter and the other glass tubes about 1 $\frac{5}{8}$ " in diameter. Such glass tubes have been found to give results comparable with those of the larger units.

The results of 17 months' operation of the larger unit with Hydrodarco are described. The flow was upward at the rate of 2 gal. per sq. ft. per minute and the bed was washed twice during the period in the manner used for rapid sand filters. In the glass tubes comparative tests were carried out using 5 types of carbon (Hydrodarco, Minchar, Woodchar, Bonechar and Nuchar), and the actions of a 48" bed of fresh carbon and of carbon taken from the larger unit after 13 months' use and revived by heating and by treatment with sodium hydroxide were tested.

The results are given in tables. It appears from these results:

1. That fairly deep beds are to be preferred, a bed 48" in depth with water applied at a

rate of 4 gal. per sq. ft. per minute reducing residual chlorine to a lower figure than a 24" bed at 2 gal. per sq. ft. per minute.

2. That either upward or downward flow can be used. The maximum rate with upward flow is about 4 gal. per sq. ft. per minute with 4-12 mesh Hydrodarco. Higher rates can be used with downward flow but friction losses are greater and more frequent washings are necessary.

3. That the most suitable form of revivification depends on what the material has adsorbed. Where loss of activity was due to gelatinous compounds clogging the pores of the carbon, revivification for dechlorination was successfully achieved by drying at 105° C. or treating with a hot solution of sodium hydroxide.

4. That materials differing widely in carbon content are suitable for dechlorination.

5. That superchlorination followed by dechlorination by active carbon removes practically all taste producing compounds likely to be found in water.

6. That 1 lb. of Hydrodarco will reduce the residual chlorine in about 30,000 gal. of water from 1.0 to less than 0.1 p.p.m. without revivification, using a carbon bed 24" deep at a rate of 2 gal. per sq. ft. per minute. By revivifying the material it is believed that 200,000 to 500,000 gal. of water may be dechlorinated per lb. of Hydrodarco.

—J. R. Baylis, *J. Am. Water Works Assn.*, 22: 1438, 1930. From *Summary of Current Literature, Water Pollution Research*, IV, 6 (June), 1931.

The Sewage Treatment Works of Zurich, Switzerland—An account is given of the sewage works of Zurich, Switzerland. The original plant, which was constructed to serve about one-third of the population so that experience could be gained for the design of the complete works, consists of rainwater overflow weir, grit chamber, 2" bar screen, sedimentation chambers, pumps for sludge, separate sludge digestion chambers, sludge drying beds and lagoons.

The effluent from the sedimentation chambers is discharged into the river Limmat and the ripened sludge is lagooned and sold as fertilizer. The main changes from the old plant in the construction of the new plant are enumerated. Cost data and diagrams of the sedimentation and digestion tanks are included.—M. Suter, *Sewage Works J.*, 2: 419, 1930. From *Summary of Current Literature*, Water Pollution Research, IV, 6 (June), 1931.

Use of Sewage Gas as City Gas—The chemical composition, the volume and dependability of supply, and the cost of sewage gas are considered with regard to its use as a city gas. Although sewage gas has a sufficiently high heating value to be useful, its slow rate of flame propagation is a disadvantage and its high specific gravity would necessitate a greater expenditure of power for pumping than in the case of the ordinary types of city gas; the flame characteristics would be greatly improved if the sewage gas were mixed with some other type of gas to increase the hydrogen content.

Sewage gas would afford a reasonably dependable source of supply but its maximum production could rarely exceed 1 per cent of that required for city gas and it would be produced in greatest quantities in the summer when it was least required. Its value to a gas company is equal to the enriching value and

today enrichment can be obtained considerably more cheaply from bunker fuel oil.

The effect of temperature on digestion and the use of sewage gas for tank heating are discussed. A great saving in plant may be obtained by maintaining the temperature of digestion tanks close to the optimum temperature for digestion, i.e., in the vicinity of 77° F. It has been found that if the sewage gas is collected and used for heating the tanks, the temperature may be maintained above 70° F. throughout the year and thus the rapidity of digestion and capacity of the plant may be greatly increased.

It is concluded that the collection of sewage gas is justified if it is burned to prevent nuisance or utilized for heating the contents of digestion tanks, but it is not justified in the United States for use as a substitute for city gas.—W. H. Fulweiler, *Sewage Works J.*, 2: 424, 1930. From *Summary of Current Literature*, Water Pollution Research, IV, 6 (June), 1931.

Refuse Disposal and Steam Power—The Huddersfield destructor was built solely for the utilization of the refuse to generate steam. The following conditions had to be met in the design of such a plant: (1) A constant output of steam per hour; (2) maximum steam production per lb. of refuse burnt; (3) a great degree of mechanization of refuse handling.

The plant as constructed is probably the most efficient steam raising refuse incineration plant in existence at present. The plant will produce a steady supply of steam hour after hour and day after day. A harder clinker is produced than usual and the manual labor used in handling the refuse is reduced to a minimum. All refuse, even dust—excepting metals—is incinerated.

The incinerator will handle 28,000 tons of refuse per year; 500 tons of

metal and 5,000 tons of clinker, besides the steam, will be recovered for sale. Innocuous dust will be the only material dumped and will amount to about 15 per cent of the total refuse.

The plant will handle 180 tons of refuse in 18 hours (calorific value—5,000 B.T.U. per lb. as charged), by means of 8 Woodall-Duckham furnace type cells. Each boiler is served by the gases from two cells. The refuse is discharged into a storage hopper below ground level from the collecting wagons. The refuse is raised from the storage hopper by means of a grab and conveyed to a rotary distributor.

From the distributor the refuse goes through a magnetic separator where the metals are removed. The metals are sent to a baling press and the other refuse is sent to an auxiliary storage pit from where it is delivered by means of a grab to the feeding hoppers. The refuse is fed to the furnaces by means of hydraulically operated rams and is burnt by means of a pre-heated high pressure air supply delivered through tuyeres placed at the lower part of the furnace.

The non-combustible portion of the refuse is converted into a hard clinker. The gases of combustion are drawn through water-tube boilers and ejected into the chimney by means of dust extracting waste-gas fans. Each boiler is fitted with dust collecting chambers and arranged so that dust can be removed during operation. The steam is supplied to the electricity department.

Each furnace cell has a hydraulically operated clinker knife and door through which the clinker is discharged into a skip. The clinker is quenched in a suitable quenching tower and then crushed and graded after passing

through a magnetic separator. The cost of the installation was £65,000.—Anon., *Surveyor*, 78, 2021: 383-386 (Oct. 17), 1930. From *Pub. Health Eng. Abstr.*, Jan. 31, 1931. Abstr. C. T. Carnahan.

Special Equipment and Careful Supervision in Los Angeles County Remove Objections to Garbage Disposal by Hog Feeding—A survey of 62 municipalities in this country indicates that the average cost of collecting garbage is \$2.94 per ton. Other data show that where garbage is disposed of by hog feeding an average of \$1.05 per ton is paid to the community by those collecting the garbage for disposal by hog feeding. Such disposal, therefore, reduces the net cost of collection to \$1.89 per ton.

There are extensive hog farms in use in Los Angeles County to serve 44 municipalities and very successful results have been secured because of expert supervision, inoculation of hogs, the use of concrete feeding platforms, suitable shelters and adequate equipment for the disposal of unconsumed garbage and manure. These results have been secured largely through the control of hog ranches by the Los Angeles County Live Stock Department.

Thirty-nine licensed ranches were operated in 1929 and only three complaints were received relative to nuisances. Two of these complaints were due to one small plant where the owner neglected to dispose of the manure properly. The third complaint related to an odor temporarily present when a compost pile was removed.—L. F. Conti, *Am. City*, 43, 6: 86-89 (Dec.), 1930. From *Pub. Health Eng. Abstr.*, Jan. 31, 1931. Abstr. C. R. Cox.

INDUSTRIAL HYGIENE

Gases in Manholes: A Survey of a Utility in Boston, Mass.—The investigation was made in the city of Boston and 19 other contiguous towns in coöperation with the Edison Electric Illuminating Co. of Boston. The survey extended over a period of 1 year during which 1,765 different manholes were tested and 4,068 individual tests made.

The workers were put to the task of devising special apparatus for testing the gases in manholes (this is described). In regard to odor as a guide, it was found that the smell test is positive in indicating rather large amounts of combustible gas, but it does not give any indication of the relative amounts present.

As a general average, 6 per cent of the manholes tested contained combustibles or sewer gas at one time or another. The majority of these were in the city of Boston; manholes in outlying districts were usually free from gas. Two districts in Boston had manholes in which the combustibles were above the upper explosive limit and represented especially dangerous conditions.

Carbon monoxide and hydrogen were present in all samples which contained combustibles in amount equal to 25 per cent of the lower explosive limit, on which complete analyses were made. It is, therefore, concluded that leakage of manufactured gas was the chief source of combustibles in the manholes during the survey. In no case was gasoline or other similar hydrocarbon detected.

Sewer gas was found in 9 samples. The amount of combustibles was always so low in these as to present no

explosion hazard, but on account of the low oxygen content such atmospheres would suffocate workmen who entered them without respiratory protection.

The results would indicate that it would be well worth while for utilities in other cities to conduct similar tests. —G. W. Jones and G. St. J. Perrott, *Report of Investigations*, U. S. Bureau of Mines, R. I. 3109: 1-16 (May), 1931. E. R. H.

Incidence of Miners' Nystagmus Among South Coast Coal Miners—While the examination of 500 South Coast miners was proceeding an opportunity was taken to determine the incidence of nystagmus among these men, to test out various methods described for its detection, and to find the value of the different methods with a view to forming standards of disability for compensation purposes.

It may be stated here that the incidence found was similar to that described by European investigators while certain of the more recent observations of Ohm on this subject were confirmed. —Charles Badham *et al.* (see previous abstract). E. R. H.

Sanitary Drinking Facilities with Special Reference to Drinking Fountains—The pamphlet contains recommendations for drinking water service stressing the importance of the type of drinking facility used, the standards of national agencies for the design of sanitary drinking fountains, and the various state laws, rules, and regulations pertaining to drinking facilities in places of employment.

One chart illustrates the state regula-

tion in regard to the prohibition of the common drinking cup in places of employment and a second chart, similar laws, regulations, and recommendations concerning the problem up to April, 1930. A selected bibliography accompanies.—Marie Correll, *Bulletin No. 87*, Women's Bureau, U. S. Department of Labor, 1931, 26 pp.

Division of Occupational Diseases, Connecticut State Department of Health—The Division has been granted a budget of \$32,152 for the biennium 1931–1933, and an additional chemist has been added to the staff, which now consists of a director, medical doctor; engineer to make surveys and technical determinations of work-room environment in the field; physical chemist for laboratory determinations; secretary; and well equipped laboratory. Additions may also be made as occasion requires. E. R. H.

The Carcinogenic Potency of Mineral Oils—In the process of manufacture of refined shale oil, the most potent fraction tested was found to be the unfinished lubricating oil. The refined oil was somewhat less potent, while the cruder products were on an average about 60 per cent less potent.

Samples of refined petroleum lubricating oils obtained from various fields of the world had widely different degrees of activity. A sample of Venezuelan oil was very potent, while Russian and Pennsylvanian samples were on an average less than one-tenth as active. Many other oils had an intermediate activity. However, two oils from the same area may have widely different activity, probably having come from different fields or having been more thoroughly refined with acid. For example, two Texas oils gave us potencies of 1 and 30, respectively.

As a rule the heavier grade oils tested were found to be less potent than

spindle oils. The amount of acid used in refining may account for the difference.

The addition of lanolin or sperm oil materially lessened the carcinogenic activity of the oils; in two cases 10 per cent lanolin reduced the potency 89 per cent.

Several saponifiable oils tested showed no carcinogenic activity; with regard to mineral oils, it appears that in general terms, the more saturated the constituent hydrocarbons the less capable were they of inducing cancer in experimental animals, the physical characteristics being similar.

The fluorescence of oils may be related to their potency. We have examined chrysene and found that, although very little soluble in the diluents used, it had a definite carcinogenic activity.—C. C. Twort and J. M. Twort, *J. Indust. Hyg.*, XIII, 6: 204–226 (June), 1931. E. R. H.

Cottonseed Oil (Milling and Refining)—The present scope and economic status of the cottonseed oil industry is given in statistics with a discussion of the types of workers and working conditions and a description or classification of jobs with their potential health hazards.

Among these are to be noted especially dust (silica being an important one), skin irritants with their corresponding skin diseases, and gossypol, a toxic body contained in cottonseeds which may be harmful through skin contact. (Illustrations accompany.)—Retail Credit Company, *Industry Report*, 6, 8: 85–94 (Aug.), 1931.

Trichlorethylene, Its Properties and Uses—In 1925, the company below named began the manufacture in this country of trichlorethylene, a solvent which has been produced in Europe for over 20 years. Of late years greater interest has appeared in this direction.

The physical and chemical properties,

specifications, principal uses and applications of the substance are given in detail. Supplementing these data, considerable space has been devoted to the present-day methods of use, such as fat and oil extraction (as from caffeine and nicotine), edible and inedible oils, bones and leather, the purification of explosives, and in analytical work.

The substance is also used in degreasing, degreasing processes, dry cleaning of textiles, wax removal from mineral oils, as a refrigerant, insecticide and fumigant, etc. It may also be mixed with certain other solvents, especially benzol and naphtha, certain precautions having to be taken.

As to physiological properties, from available evidence, trichlorethylene is not cumulative in its effect on the human system and produces no permanent impairment of health as a result of ordinary exposures to its vapors. Excessive exposure may produce intoxicating effects. These, however, disappear quickly on access to fresh air, since "Tri" is rapidly eliminated from the body. So far as relative toxicity is concerned, it is less dangerous than chloroform and many other chlorinated hydrocarbons and a number of petroleum solvents.

During the 6 years in which "Tri" has been manufactured by the present company, there is no record of any workman being so affected by its vapors that he found it necessary to obtain first aid or medical assistance.

Regardless of the comparative physiological action of different solvents, the equipment in which these solvents are to be used should be scientifically designed and built so that the health of operators is not endangered. Since small leakage or loss may occur even in the best designed plants, it is well to know the relative toxicity of different solvents, as indicated in various toxicity tables. These tables are based on reliable data but they all suffer from one

drawback—there is no consideration of the human element. If any one of them is handled in a negligent manner, the health hazard is increased tremendously. The relative toxicity of various solvents including "Tri" is given in an Appendix to the present work.—The Roessler & Hasslacher Chemical Company, Empire State Building, New York, N. Y., 1931, 38 pp. E. R. H.

Benzol (Benzene) Poisoning—

This is a new investigation of the toxicity of benzene and benzene impurities. A concise statement is made covering the history, chemistry, and industrial uses of benzene, acute benzene poisoning, chronic benzene poisoning, benzene dermatitis, and the medico legal aspects of such poisoning.

New experimental work with benzene is discussed in considerable detail, including a highly purified product, the toxicity of impurities and of homologues of benzene. Protocols of animal experiments, charts and comments constitute the chief body of the monograph.

Experimental work has clearly demonstrated toxic manifestations from all benzenes used, the lesions simulating those known to characterize benzene poisoning in man. Highly purified benzol is no less toxic than any other variety studied, and has produced a higher death ratio than any other benzene. No differences in manifestations among animals have suggested different types of lesions resulting from different grades of benzene. Such lesions as have been obtained have been relatively uniform. Benzene is in itself a toxic entity. All evidences of toxicity from benzene solutions containing rubber or similar sulphur bearing substances are to the effect that the benzene content is solely responsible.

Contrary to the usual beliefs, leucopenia does not invariably accompany benzene poisoning, and even severe poisoning may exist in the presence of

normal or above normal numbers (below 5,000). Single counts are of restricted value. A sustained leucopenia in suspected benzene poisoning is of diagnostic value, but in itself is not pathognomonic.

In the examination of tissues, two lesions stand out as of special significance: (a) nephritis with a special point of attack in the convoluted tubules, though not necessarily limited to them, but so unlike the usual nephritis as to constitute diagnostic evidence; and (b) hypertrophy of the stomach, most observable in the pyloric region. Acute ulcers have been observed, principally on the greater curvature near the cardiac end in the stomach (rabbits). Infections play an important part in determining fatality in benzene poisoning in rabbits, and, while several animals died from benzene poisoning itself, it is thought that infection is more than a terminal process in this form of poisoning.

Studies were likewise made of the toxicity of impurities of benzene, viz., acetonitrile, thiophene, amylene, methyl disulphide, and carbon bisulphide. Rabbits were again employed as the test animals. All chemicals were administered through inhalation. With respect to these, the results do not provide any evidence tending to place the burden of benzene toxicity upon its impurities.

The relative toxicity of 14 homologues of benzene, the principal ones being toluene and xylene, is commented upon and experimental evidences adduced to support the current belief that wherever practical toluene and xylene should be substituted for benzene because of lessened general toxicity.

Several pages are devoted to methods for the determination of benzene in the form of vapors admixed with air, likewise a section on the treatment of benzene poisoning and another upon practical protection. An exhaustive bibliography accompanies.—Carey P. Mc-

Cord and collaborators, mimeographed monograph, Industrial Health Conservancy Laboratories, Cincinnati, 1931, 78 pp.

Butchers' Dermatitis—From the author's summary:

Butchers' dermatitis, characterized principally by erythematous areas on the hands followed by the appearance and subsequent eruption of pinhead vesicles, and accompanied by considerable itching as a symptom, is an occupational disease largely affecting butchers and inspectors who handle freshly killed carcasses.

The lesions, which first appear on the webs of the fingers and spread to the sides and backs of the fingers and to the backs of the hands as far as the wrists, may extend up the arms as far as the elbows, and in exceptional cases may spread to other parts of the body such as the chest, abdomen, legs, and face.

The affection does not appear immediately upon the exposure of susceptible persons, but usually makes its appearance after an initial period of exposure varying from 3 to 30 days, during which time susceptible persons presumably become sensitized to the tissues and fluids of swine, cattle, and sheep.

While certain persons make a rapid recovery following the first attack, with or without treatment, others develop repeated attacks while the exposure to the inciting cause is continued; in some persons the susceptibility lasts for several years. The available evidence indicates that many seasoned workers lose their susceptibility to this affection in the course of time.

While most susceptible persons appear to become fairly equally sensitized to the various classes of meat food animals that are slaughtered in abattoirs, certain persons exhibit a specific susceptibility to one or two classes of these

animals and are unaffected by contact with others.

The dermatitis may be checked by various local applications commonly used in treating related skin troubles in which there are no constitutional symptoms.

On the basis of available evidence, frequent washing of the hands in cold running water, thorough scrubbing of the hands with soap and brush at the end of the day's work, and coating the hands with vaseline or other ointments before beginning the day's work are, in most cases, effective prophylactic procedures.—Benjamin Schwartz, *J. Indust. Hyg.*, 13, 7: 233–243 (Sept.), 1931.

Observations on the Working Capacity of Coal Miners in Relation to Atmospheric Conditions—From the authors' summary: The influence of atmospheric conditions on working capacity was measured by noting the duration of rest pauses taken from work. Observations were made on 304 men for an average period of 97 minutes each, or for a total of nearly 500 working hours.

The amount of time taken for rests was more closely associated with the dry bulb factor than with the wet. The association between rest pauses and atmospheric conditions is not a very close one, and does not enable one to forecast what amount of rest any particular miner, or small body of miners, would take under given atmospheric conditions. There are evidently other factors which have a more powerful influence on production than atmospheric conditions, which might nullify the good effects of any improvement in these conditions.

Neither the relative nor the absolute humidity of the air seems to have any definite effect on the amount of time

taken for rests when the dry kata cooling power is kept constant.

The observations suggested that in a hot, dry mine, working conditions might be improved by the use of artificial humidification. An experiment in this method of air conditioning was carried out, but owing to certain unforeseen and unavoidable circumstances, the results were, practically speaking, completely negative.

It is concluded that if the relative influences of the dry and wet bulb factors on working capacity are to be accurately assessed, the matter must be investigated under laboratory conditions.—T. Bedford and C. G. Warner, *J. Indust. Hyg.*, 13, 7: 252–260 (Sept.), 1931.
E. R. H.

A Study of Dysmenorrhea at the Home Office of the Metropolitan Life Insurance Company—Author's summary:

1. Severe cases of dysmenorrhea (congestive and infantile type) can be improved, and about 50 per cent can be cured.

2. The best results are obtained by using daily both the Mosher and setting-up exercises.

3. Constipation plays a large part in causing dysmenorrhea and necessitates careful regulation of diet.

4. Psychologic factors, such as self-discipline, also play a part in treatment for dysmenorrhea.

5. There has been a considerable saving in time lost, both from absences from work because of dysmenorrhea and from visits to the rest rooms at the Home Office of the Metropolitan Life Insurance Company, through the treatment of severe dysmenorrhea and through watchful supervision of the milder cases.—Ruth E. Ewing, *J. Indust. Hyg.*, 13, 7: 244–251 (Sept.), 1931.

FOOD, DRUGS AND NUTRITION

Relation of Manganese to the Nutrition of the Mouse—While observations indicate a wide distribution of manganese in the vegetable and animal kingdom and it is definitely shown by recent work that manganese plays no rôle in hemoglobin formation, it is concluded that it does have a definite physiological action, perhaps in connection with reproduction.

The authors have found it possible to make preparations of casein, sugars, salt, vitamins A and D, practically manganese-free but in view of the difficulty of securing manganese-free vitamin B complex, resort was had to milk which contains approximately 0.02 mg. Mn per liter.

Mice were the experimental animals in order to conserve the supply of manganese-deficient foods.

Stock females were transferred to individual, raised, screen cages before the young mice were born and every precaution taken against contamination of any food material with manganese during the weaning period. After weaning, the young mice were divided into two groups, one receiving milk supplemented with 0.15 mg. iron and 0.01 mg. copper daily, and the other the same diet with addition of magnesium chloride to supply each mouse with 0.01 mg. of Mn daily.

In some instances, the milk ration was supplemented by a practically manganese-free mixture of lactose, butter oil and casein. With these diets, the growth curves indicate that the manganese had a definite effect on growth. As a typical result, in the case of 2 females from the same litter after 7 weeks on the experimental ration, 1 mouse weighed 19.1 gm. and the other on the

manganese-free diet weighed 12.7 gm.

A study of the ovulatory rhythm shows that manganese is closely connected with the reproductive organs. In the case of the mice receiving no manganese, in only 1 mouse out of 5 did the estrus cycle make its appearance—then only twice. With manganese during the same period of observation, the number of estrus cycles increased from 3 to 8 and 1 mouse gave birth to 5 young when 134 days old. The frequency of the cycles in the manganese group appears to be approximately normal. While it is concluded that manganese has a distinct influence on the ovarian activity, no opinion is expressed as to the mechanism of this action.—A. R. Kemmerer, C. A. Elvehjem, and E. B. Hart, *J. Biol Chem.*, 92: 623 (Aug.), 1931.

Effects of Deprivation of Manganese in the Rat—As a preliminary to the study of the deficiency of manganese in the diet, it was necessary first to provide an adequate diet of manganese-free food materials. By the spectrographic method of examination of a wide variety of foodstuffs, the following food dietary factors were found practically manganese-free: starch, sucrose, casein, butter fat, vitamins A, D, and E, sodium chloride, calcium lactate, and K_2HPO_4 , NaH_2PO_4 and $CaH_4(PO_3)_2$.

Essential dietary factors such as supplementary proteins, vitamins B and G, an iron salt, and a magnesium salt not available in a manganese-free condition were prepared by methods devised by the authors so as to be practically manganese-free. The vitamins and supplementary proteins were prepared by ex-

tracting yeast in 50 per cent alcohol and the iron and magnesium salt were the hydroxides.

Four different diets were given the young rats: first, the diet manganese-free; second, the control containing the substances with the natural content of manganese; third, manganese-free ration plus 0.005 per cent manganese as $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$, approximating the average amount in animal and vegetable tissues; and, fourth, manganese-free diet plus 0.05 per cent manganese. All diets contained 15 drops per kilo of Viosterol. All precautions were taken to prevent contamination of animals or cages with manganese.

On all four diets, young rats grew to maturity and those on the manganese-free diet did not differ materially from well nourished rats on a diet continued 7 months or more. The organs of the rats on the manganese-free diet as well as the new-born rats and rats 15 days old of mothers on the manganese-free diet showed no manganese. Manganese is present both in the organs and in the bodies of young rats on normal diets, indicating transmission of manganese through the placenta.

Absence of manganese did not interfere with hemoglobin formation, nor was the addition of manganese able to effect hemoglobin regeneration in the case of experimental anemia. Females on the manganese-free diet appear to have normal estrual cycles and normal litters when mated with normal males. The females, however, failed to suckle the young in 58 out of 59 cases. The same females when given foster young from known litters failed in 8 out of 10 cases to suckle them.

Females from stock colonies showed little interest in the young of manganese-free mothers, although 7 out of 107 manganese-free young were so reared. These were undersized in spite of having secured the necessary food. Male rats show no abnormality until about

the 100th day when testicular degeneration appears with progressive atrophy until complete sterility results. Sexual potency in the male was restored by the addition of manganese to the diet.

The authors conclude as a result of similar clinical evidence in human subjects that manganese is essential to the production in the hypophysis of a hormone which regulates the function of the testes in the male and the mammary tissue in the female.—Elsa R. Orent and E. V. McCollum, *J. Biol. Chem.*, 92: 651 (Aug.), 1931.

Beneficial Effects of Fat in High Sucrose Diets when the Requirements for Antineuritic Vitamin B and the Fat-Soluble Vitamin Are Fully Satisfied—These authors reported previously (*J. Biol. Chem.*, 83: 269, 1929) that the presence of dietary fat reduces requirements for the antineuritic vitamin. This work was undertaken to determine whether diets improved by vitamin B can be further improved by additional fat.

Female rats, 21 days old, reared in individual cages on raised wire screens, were the experimental animals. The fat-free diet consisted of specially treated casein, autoclaved yeast, sugar, and salt mixture. The fat diets were on the basis of 25 per cent fat with adjustment of sugar and casein levels to maintain approximately the same nutritive ratio. The fats were lard, coconut oil, synthetic cottonseed and synthetic coconut oil. The synthetic fats were prepared by saponification of the natural fats and esterification of the fatty acid with redistilled glycerol.

Brewer's yeast, ether-extracted wheat germ and rice germ, and alcoholic extracts of rice bran and rice polish were used as sources of vitamin B.

Three experimental series are recorded. In each of these vitamin B was fed at many times the level for the requirements of the rat. In the first

experiment, growth of animals on the fat-free diet was inferior to the diet containing 25 per cent of lard, although both were supplemented with vitamin B from the wheat and rice germ and with the extracts of rice bran and rice polish.

This series disclosed the fact that rats on the normal stock diet were definitely inferior to those receiving the fat supplement and not superior to the fat-free diet.

In the second series, the 25 per cent fat component was synthetic cottonseed oil. This series shows beneficial effects of the diet in those cases where the vitamin B supplement was brewer's yeast or rice polish extract.

In the third series, with rice bran and rice polish extract as vitamin B additions, the rats receiving the natural coconut oil and lard adjustment were superior to those on the fat-free diet. The series in which the animals received a high supplement of rice bran extract was allowed to run a year, and while the animals on the fat-free diet showed no marked deficiency at the end of this time, they were definitely inferior to those receiving fat as is evidenced by coarser fur, tendency toward skin dryness, and lower body weight.

The authors conclude that the improvement is not due to fat-soluble vitamins as the same improvement was shown by synthetic fats and that vitamins A, D, E and F were abundant in all diets.—Herbert M. Evans and Samuel Lepkovsky, *J. Biol. Chem.*, 92: 615 (Aug.), 1931.

Distribution of Manganese in Foods—It was the aim of this investigation to supplement data already reported. The procedure given by Davidson and Gapen (*A. O. A. C.*, XII: 310, 1929) was followed in the analyses of samples containing 0.1 mg. or more of manganese, while foodstuffs containing very small amounts of manganese were analyzed according to the modification

reported by the authors in the *Journal of Biological Chemistry* (88: 347, 1930).

The manganese content of 83 representative food materials is given. The concentrations range from 0.028 mg. per liter of milk to 49.9 mg. per kilo of bran flakes. Thirty-six of the materials contained less than 1 mg., 25 contained from 1 to 5 mg., and only 22 more than 5 mg. per kilo of fresh material.

Arranged in descending order with respect to their manganese content, 12 classes of foods representing 138 food materials appear as follows: nuts; cereals and their products; dried legume seeds; green leafy vegetables; dried fruits; roots, tubers and stalks; fresh fruits; non-leafy vegetables; animal tissue; poultry and poultry products; dairy products; and fish and sea foods. Since blueberries were found to contain such an enormous amount of manganese (314.9 mg. per kg. dry basis) the average for fresh fruits was given both with and without the blueberry value. In typical American diets, cereals and their products contribute the largest proportion of the manganese intake.—W. H. Peterson and J. T. Skinner, *J. Nutrition*, 4: 419 (Sept.), 1931.

Absorption of Aluminum Compounds—The absorption and retention of aluminum were studied in a group of rats which were raised from weaning to maturity on a diet which contained 0.6 per cent of aluminum chloride, which is equivalent to 600 p.p.m. of the element aluminum.

After 3 months 6 rats were killed, at which time they had more than quadrupled their weight. A table shows concentrations of 0.2 to 1.0 p.p.m. of aluminum in the liver, kidneys, spleen, and testes or ovaries of rats raised on diets containing 600 p.p.m. of aluminum as compared with 0.05 to 1.0 p.p.m. the concentrations of aluminum previously found in the same organs of rats raised

on standard stock diets. This shows a difference so small as to warrant the conclusions that aluminum present in the diet is not absorbed and deposited, as has been contended by Underhill *et al.* (*Am. J. Physiol.*, 90, 1929).—Dee Tourtellotte and O. S. Rask, *Am. J. Hyg.*, 14: 225 (July), 1931.

Effect of Vitamin B Deficiency upon the Vitamin A Reserves of the Rat—It has been previously shown (*Biochem. J.*, 25: 275, 1931) that when rats are given diets rich in carotene, vitamin A may accumulate in the liver in amounts that seem great compared with the minimal daily requirements. This is a report of a further study of the effect of vitamin B deficiency upon the vitamin A reserve of the rat.

The experimental animals used were adult albino rats which had been reared to maturity on a complete synthetic diet and subsequently maintained for about 200 days upon a diet rich in carotene. Under these conditions the vitamin A reserves of the liver had been found to be remarkably constant between individuals. The rats were then exposed to diets deficient in the vitamin B complex until severe emaciation resulted, after which post-mortem examination was made both as to the extent of the remaining body fat and the amount of vitamin A still contained in the liver oils.

Rat 1 was used as a control and was

kept on the complete red palm oil diet.

Rat 2 was transferred from the complete diet to one deficient in vitamin B complex which still contained red palm oil (Glaxo caseinogen 20 per cent, cane sugar 60 per cent, salt 5 per cent, red palm oil 15 per cent). On this diet the rat declined rapidly and died after 48 days. Post-mortem showed complete absence of fat depôts and general emaciation.

Rat 3 was transferred from the complete diet to one similar to that given to rat 2 except that arachis oil replaced the red palm oil, making the diet completely free from vitamins. After 35 days the rat, being extremely emaciated, was killed. Post-mortem examination revealed that the remains of the fat depôts were very scanty.

Rat 4 received the same diet as rat 3 but was killed after a longer period. There was a complete absence of intraperitoneal fat. Analyses were made separately of the liver, the intestinal tract and contents, the pelt and the remainder of the carcass.

From the results reported, it is evident that the high reserves of vitamin A which the rat is able to store in the liver when fed on a diet rich in carotene are not depleted when it is concurrently or subsequently suffering from lack of the vitamin B complex in spite of the severe drain on the body fat.—William John Dann and Thomas Moore, *Biochem. J.*, 25: 914, 1931.

CHILD HYGIENE

HEALTH OF THE SCHOOL CHILD

CHILDREN, at the time of school entrance, are very unequally conditioned physically, mentally, and emotionally. This difference arises primarily from hereditary factors, modified by social environment, nutrition, infections, and various handicaps due to accident or disease. The school has assumed that its primary function is to detect the mental differences in children and provide for their formal education in either graded or ungraded classes. This assumption is a hang-over from the old classical conception of education, namely, that the mind was the first consideration of the school and the body an encumbrance. We know now that mind and body are intimately related and that the whole child should be the concern of school authorities.

It is futile to try to force upon children the education provided by the school if handicaps, physical or mental, exist; if, for example, the child is so poorly nourished as to be hyper-excitable or easily fatigued, his mind cannot be receptive.

Ideally, there should be a progressive health program for the child from his prenatal life right to time of school entrance. If we could open the way for applying to the preschool child the technics we know would be effective, the school would be relieved of a great deal of its difficulty in classifying children and looking after defects at school entrance. Our best efforts should be concentrated upon the preschool child in order to prepare it properly for school. While the school may, in self defense, promote preschool examinations to detect defects, it is really the function of the local health department to follow all children who go to child health centers,

until they enter school. It would be ideal if the completed health record of the child could accompany it right into the school. This is too much to expect, probably, in an age when migration is so constant. It is even more difficult to keep track of the preschool children than of school children.

There are, however, certain protective measures which should be carried out thoroughly for the preschool child. Vaccination against smallpox and immunization against diphtheria should be done by all means before school entrance. An unprotected child population is especially susceptible to smallpox, and it has been stated that 58.5 per cent of the deaths from diphtheria occur under 5 years of age, and 86.5 per cent under 10 years.

At this season many city health departments are issuing pamphlets regarding the health of the school child and pointing out the necessity of a thorough physical and mental examination at school entrance. A recent bulletin of the Minneapolis Division of Public Health¹ sets forth this problem of the school entrant. It states:

The three essentials every child must have for satisfactory progress in education are: proper vision, good hearing, and the growing ability to think. Whatever interferes with these three cardinal functions results in either breakdown or unnecessarily laborious effort.

The correction of existing faulty conditions, such as bad teeth and poor tonsils; the proper treatment of functional conditions such as poor nutrition, unstable nerves, and simple heart disturbances calling for the teaching, by precept and example, of proper health and social habits should not be delayed until the kindergarten age is reached. The protection of the individual against the liability to infections tending toward the establishment of disease processes may be met by such preventive measures as timely vaccination and

inoculation properly performed during the first or second year of life. If these precautions have been neglected until the kindergarten age is reached, it should be a matter of grave concern and of rectification then. Contagious diseases leave their mark upon the growth and structure and functions of the child, and frequently are handicapping millstones, dragging the child down into the mire of incomplete productiveness throughout his entire life.

In its report, *Communicable Disease Control*, a committee² of the White House Conference on Child Health and Protection pointed out that:

School children are the group most easily reached. The school was at one time regarded as a place of opportunity for children to contract disease. It is now known that a school with proper health supervision, ordinarily, is one of the safest places for the child.

The committee recommends early immunization against smallpox and diphtheria and, as general control measures among school children, the following:

1. Morning inspection of every child by nurse or teacher who is familiar with ordinary signs of disease
2. All suspects referred to the school physician, local health officer, or family physician for diagnosis
3. Exclude suspects and recognized cases until certified by competent authority as safe to return

A matter of prime importance during the present depression is the strengthening of child labor laws and the rigid application of their provisions. This is closely related to the school health problem. The National Child Labor Committee³ points out that:

Cutting short children's schooling for work benefits no one. It not only limits their edu-

cation but may impair their health. The competition of children in industry, moreover, tends to depress wage rates, lower standards of living, and aggravate unemployment. Even in the year 1930-1931, with millions of adults unable to find work, in 23 states and some additional cities reporting to the U. S. Children's Bureau, permits were issued to 103,000 children 14 and 15 years of age to enter industry.

It is also of great concern that this same committee is obliged to report:

Most children under 16 are so immature and reckless, so easily fatigued, and have such poor muscular coördination that no industrial employment, no work in the vicinity of machines, even when they do not themselves operate them, no employment in transportation, is free from hazard. Thousands of 14- and 15-year old children are injured in industry every year, some of them being killed or maimed for life. The only effective safeguard is to prohibit all industrial employment under 16 years.

To prevent this costly toll of industrial accidents, burdensome to industry as well as to the injured children, laws must be enacted with the support of public opinion which will keep all children under 16 years of age in school, and which will prohibit the employment of minors between 16 and 18 years of age in dangerous occupations. Such a course would serve the triple purpose of assuring to our young people a fully-rounded education, safeguarding them against industrial injury, and relieving the pressure of child competition in the employment market.

PUBLIC HEALTH NURSING*

Over the Top with the A. N. A.—In 1896 a little group of far sighted nurses organized themselves into the American Nurses' Association. In January, 1931, their membership numbered 86,000 when they launched a drive for 100,000 members. Early in September on the thirty-fifth anniversary of their organization at the end of the drive there were 105,000 members. This is probably the largest professional organization of the women of one country in the world.

Effectively functioning state associations in every state of the Union, in the District of Columbia and in Hawaii and Porto Rico give evidence of thorough organization. Janet Geister, Director of the American Nurses' Association, says:

But organization is only a prelude to program. What cannot a hundred thousand nurses do! For 5 years we have been making a self study to find our true status. The first step in shaping a program has been accomplished. The diagnosis has been made. We know pretty well what our problems are. The next step is treatment. What are we going to do about it? and who shall do it? We look to the national organization for guidance and leadership. But it is the local groups, close to actual conditions, who must do the work. In the national office, plans are under way now for making practical suggestions for activities in state and district and alumnae groups during the coming year. Nursing problems are universal. They differ locally only in degree. The national office is a clearing house through which emanate committee and board actions, standards, objectives and programs. In the heart of the individual nurse lies the answer to the future of nursing. The American Nurses' Association is built out of the heart of the nurse herself

working in her alumnae district and state—a glorious task, for we are meeting human needs.

—*Bull.*, American Nurses' Association, Sept., 1931.

N. O. P. H. N. Membership Drive—The increasing demands constantly being made on the special committees of the National Organization for Public Health Nursing which make studies of costs, staff education, statistics, mental hygiene, school and industrial nursing, etc., as well as additional requests for different kinds of institutes, have made it extremely necessary for the organization to extend its membership to make all these services more widely available.

It is estimated that fewer than one-fourth of all the public health nurses in the country are members of the N. O. P. H. N., and since the services of the organization cannot be duplicated by any other agency, not only every public health nurse, but every lay person interested in health conditions throughout the country should give his or her support.

Mary Sewall Gardner is chairman of a Membership Committee now being organized. The campaign starts in October and will end at the biennial convention in San Antonio, Tex., next April.—N. O. P. H. N. *News Release*, Oct. 1, 1931.

A Twenty-one Months' Coöperative Course in Public Health Nursing—This course is offered jointly by the School of Applied Social Sciences of Western Reserve University and the Cleveland Visiting Nurse Association, beginning this fall. It covers the regular 9-months program for the first year, followed by appointment to a junior staff position with the visiting nurse as-

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

sociation; it is planned for nurses who want to begin preparation for public health nursing immediately after graduating from training schools; they are given a time allowance for advanced study. In the second year there is a required seminar in public health nursing each semester, and one elective course to be chosen from the regular curriculum.

The school still continues to give an elective in rural nursing for well qualified students. This includes 3 months of rural field experience and also courses in rural sociology and rural government. The Board of Health of Lorain County, with headquarters at Oberlin, O., is co-operating with the school in giving this course (Nurses as Social Workers, *Survey* (Midmonthly), Sept., 1931, p. 556).

Public health nursing leaders will watch this experiment with interest, as they have felt that students graduating from the 9-months public health nursing courses needed staff experience before launching out for themselves; yet they were just as conscious that those nurses with staff experience alone needed a theoretical course. The new Cleveland course ought to be just the preparation we are all desiring for public health nurses.

Board Education 1931-1932—The representative of public health nursing board members on the staff of the N. O. P. H. N. is constantly asked while in the field how to educate board members, how to inform new committee members about the work and their responsibilities, and what the new trends are in public health nursing. These lay people, responsible for carrying on and promoting the work of public health nursing associations, know they cannot make a real contribution unless they are well informed.

To meet this need the Board and Committee Members' Section and the staff of the N. O. P. H. N. have out-

lined two courses of study, which take the form of two series of discussion topics—one for board members of urban public health nursing organizations; the other for rural or county committees.

There will be 8 topics and on the first of each month your president or chairman of the education committee, or some other person whom you designate as responsible for this program, will receive the subject for study with suggested readings and questions raised for discussion. Our hope is that the education committee will take this topic, read the references, work up a short résumé of the material and present it at board meeting, raising some of the questions for discussion, letting others come from the floor. Do not pass this job to the nurse director to do for you! She will be at the board meeting to aid in the discussion and handle the professional angles which we as lay people do not always know about or understand, but let us do the preparation ourselves. The whole trend in modern education is toward individual study and we all know that the thing we have read about or looked up for ourselves will become a part of our knowledge more readily than if some one else does the work for us.

The topics chosen for eight months are as follows:

FOR CITY PUBLIC HEALTH NURSING GROUPS

1. Generalized public health nursing programs
2. Standards and qualifications for public health nursing positions, staff education, further opportunities, etc.
3. A community health program
4. Relationship to medical profession
5. Tuberculosis nursing
6. Social hygiene as a part of a public health nursing program
7. Industrial nursing
8. Records, statistics and analysis of costs

FOR COUNTY AND RURAL GROUPS

1. A health survey of your community
2. The State department of health
3. Full-time county health units
4. Public health nursing—history and present standards and developments
5. Rural sanitation
6. Maternity, infancy and preschool program

7. School health
8. Communicable disease control—tuberculosis and venereal disease

Board members interested in receiving this series of topics to study this winter write to Evelyn Davis, National Or-

ganization for Public Health Nursing, 450 Seventh Avenue, New York, N. Y. —Board Education 1931–1932. Board and Committee Members' Forum, *Pub. Health Nurs.*, XIII, 9: 447, 448 (Sept.), 1931.

EDUCATION AND PUBLICITY*

Lantern Slide Making—Poor lantern slides are usually worse than no slides at all. Add skill in photography to a knowledge of slide technic and the result should be photographically good slides. The "know how" is supplied by *Lantern Slides: How To Make And Color Them*, issued free by Eastman Kodak Company, Rochester.

The use of lettering calls for future discussion, but the maker of the too well known "advertising slide" cannot be trusted to produce an educational slide without detailed supervision. No one in the health field would allow a printer to lay out a page with the weird combination so common in advertising slides—several families of letters, irregular arrangement, irrelevant ornament (usually not ornamental), several colors (sometimes harmonious), all thrown together to make a picture puzzle. If not acceptable in printed form, how can we approve such material when displayed only for a few seconds?

Born: November, 1921—Ten years ago this month the first sessions of the present Public Health Education Section were held as part of the New York meeting of the A. P. H. A.

The thanks of the Section are due to the then executive secretary, A. W. Hedrich, who invited Mr. and Mrs.

Routzahn to organize two sessions on health education and publicity. The *JOURNAL* for April, 1922, gave fairly full reports of these sessions on the topics: "Motion Pictures" and "How to Further Progress in Health Education and Publicity."

Familiar names appeared in the lists of speakers: Turner, Osborn, Ellis, Meyer, Kleinschmidt, Jacobs, Snow, Dinwiddie, Dealey, Rickards, Marcus, Evans, Miss Rose, Mrs. Routzahn; with Evart G. Routzahn serving as chairman.

At that time Dr. Lee K. Frankel was elected the first chairman of the new section which lived for several years on a provisional basis, and then was given permanent status.

Less than 10 years after the first sessions in New York the Section was reported at Montreal to have 339 members and 44 fellows—and 10 fellows were elected in September. We are growing up.

Models, Flashing Lights and Pictures—How much there was to study at the annual meeting of the A. P. H. A. is emphasized by the record below of the displays at Health Education and Publicity Headquarters under the auspices of the Public Health Education Section.

Three solid models showing the trends in tuberculosis, diphtheria, and typhoid death rates in Massachusetts over the last 75 years. . . . They clearly illustrate in an interesting

manner the application of the three-dimensional graph in public health education. (Exhibited by Harvard School of Public Health.)

Copies of annual health department reports of cities, counties, and states, selected by the Sub-committee on Health Reports of the Committee on Administrative Practice of the A. P. H. A., as among the best of the year. Number of copies published, with costs, were indicated on the title pages.

Photographs of the new Deutsches Hygiene Museum of Dresden. The photographs show exterior and interior views of the museum building as well as of the vast number of wax, glass, and plaster models which it houses. They were loaned for this occasion by the Milbank Memorial Fund and by the Metropolitan Life Insurance Company, from the collection of the late Dr. Lee K. Frankel.

The White House Conference on Child Health and Protection exhibit of publications and charts.

How a health department cuts costs in the production of forms, sanitary regulations, reports, and monthly bulletins, was illustrated by the display of the Middletown, N. Y., Health Department.

"Something for idle minds in Clinic waiting rooms," exhibited by Cleveland Health Council, Ethel Hanson in charge. "Health Flashes" appeared as lantern slides or film strip, the one colored, the other uncolored.

You press a button and ring a bell, if you have selected the correct answer among four, of which only one is correct—on the Electric Questioner devised by the Racine (Wis.) Health Dept. The device is a picture frame

designed to hold and display a printed card bearing a question of public health significance, and four answers—of which one is correct and three represent current erroneous beliefs. Any number of question-and-answer cards can be arranged. There is a push-button opposite each answer, and a 4-point switch allows any button to be energized while the others remain "dead," thus allowing the correct answer to appear in any desired position. A door-bell and 110-6 volt transformer completes the wiring.

An album of photographs illustrating the Shanghai anti-cholera parade organized by Dr. W. W. Peter.

A collection of diphtheria educational material shown by Marie Kirwan of State Charities Aid Association, New York.

The Clean-Up Campaign (Cleveland Health Council), Early Diagnosis and Christmas Seal Campaign (National Tuberculosis Association), Smallpox Campaign (Racine Health Department).

Educational material by National Dairy Council and Metropolitan Life Insurance Company.

A classified collection of *Better Health* and leaflets reprinted from same, by Syracuse Department of Health.

A large portfolio, the original presentation of the work of the Detroit Health Department as its winning entry in the 1930 Inter-chamber Health Contest.

The Syndicated Health Bulletin of the A. P. H. A.

A series of classified portfolios (National Organization for Public Health Nursing) containing well selected examples of printed matter primarily for nursing organizations but of general interest to health workers.

The 10 portfolios of classified health education samples from departments and associations, and the 50 portfolios of helps and samples of examples of many types shown by Mr. Routzahn, chairman of the Education and Publicity Headquarters Committee.

In Windsor Hall—In addition to the above the main exhibit hall at Montreal contained numerous displays of interest to readers of this department. Among these were: American Society for the Control of Cancer, *Canadian Public Health Journal*, Metropolitan Life Insurance Co., *Municipal Sanitation*, National Dairy Council, Syndicated Health Bulletin (with John

Hall, of course), Victorian Order of Nurses for Canada.

Something To Do Something About—Past Chairman Howard Green when invited to write a "message" for this department naturally emphasized a point of view he sought to bring out in our 1931 program.

The second session of the Public Health Education Section at Montreal was designed to bring out a few of the simple facts known by other sections of the American Public Health Association and to demonstrate how these facts should be used to educate the public and to motivate it to action. Certain sections of the Association are primarily fact-finding; at least, the members of these sections are in constant touch with the newer demonstrated public health facts. Other sections of the Association are made up largely of persons whose chief duty it is to apply these facts in the demonstration of public health work.

The individuals making up the Public Health Education Section are chiefly concerned with aiding the producer of facts on the one hand, and the demonstrator or utilizer of facts on the other hand, and with getting the general public, various professional groups, and others, to recognize these fundamental facts and to respect and apply them for the improvement of individual health and the protection of community life. The Public Health Education Section therefore is allied with those who know the facts and those who individually and collectively promote their use for the benefit of public health. It is a well recognized fact that the general public knows more than it *does*. The health educator has a real problem in extracting the facts, in making them available, and in making the general public not only know them but recognize their value and apply them to their daily life and to the health of the community.

A State-Wide Publicity Kit—For some years the National Tuberculosis Association has prepared "publicity kits" for the Christmas Seal and Early Diagnosis Campaigns. These have included detailed plans and much ready-made material for local use.

Now there comes from the Oregon Tuberculosis Association, Fitzpatrick Block, Portland, a kit for the fall of 1931 for county units, county nurses, county public health associations.

This Educational Kit has been prepared as an aid to those interested in keeping the people of their county informed of the services and activities of their public health agencies.

The accompanying letter states the urgent need for more and better publicity which exists in many parts of the country:

We are all alive to the need for exceptional effort this fall to retain in county budgets the necessary appropriations for county and school physicians and nurses. Individual jobs as well as the service generally will be at the mercy of tax-reductionists this fall.

A more intelligent appreciation of the value of our county public health machinery must be instilled into the mind and heart of everyone if we are to stave off collapse in some communities. A comprehensive educational program reaching every corner of your territory is absolutely essential to bring this about. Some school and county nursing appropriations have already come under the knife.

The kit outlines a calendar for the fall months, suggesting statistical and other data illustrating the "wide range of the nurses' work," "services of volunteers," "results of services," and "cost of service."

Along with the above are specific suggestions as to the use of the material in newspapers, in talks, by handbills, charts, window displays, radio, etc.

Additional sheets suggest sources for securing data and help in preparing talks and writing copy; suggestions as to use of amateur movies and other special mediums; and offer three ready-made news stories with blanks for filling in local names and facts. A copy for 10 cents sent to the Oregon Tuberculosis Association.

Other state associations and departments would be inclined to provide a similar service if encouraged by requests from local workers.

They Need Help—The initiative for 1931-1932 in Public Health Education Section rests upon the new group of officers—but theirs is not the whole responsibility.

Chairman, Iago Galdston, M.D., 2 East 103d St., New York, N. Y.

Vice-Chairman, Elizabeth C. Nickerson

Secretary, Raymond S. Patterson, Ph.D., John Hancock Life Insurance Co., Boston, Mass.

Section Council:

Training and Personnel Committee, Mary
S. Routzahn

A Contest in Posture—Seeking a health education plan for awards to be made on their annual Tuberculosis Field Day, the Tuberculosis and Health Society of St. Louis conducted a posture contest. Charles A. Freck of the Society describes the plan in detail:

We secured in our own office building a suite of two rooms. The larger was divided, the front half being used for a waiting room and registration room, the rear part for a dressing room. Adjoining was the photographer's "studio." We constructed a shadow-graph 6 feet square of two sheets of architect's tracing cloth behind which was a bank of 100-watt bulbs. An ordinary photographer's camera was placed 12 feet in front of this screen. Three children stood between the camera and the screen and were photographed. Instead of photographic plates, we used bromide paper which gave us excellent results although we got only a single print.

Three days were allotted; the first for boys, the second for girls, the morning of the third for colored boys and the afternoon for girls. Some 50 organizations received a handbill announcement. The whole contest was planned and promoted in 3 weeks. One hundred and seventy-five children came. No colored children entered.

The photographs were identified by means of metal house numbers which were hung

above the child's head to correspond with the number placed on his registration card. After the paper was developed, photographs were separated and distributed among the examining committee of 4 physicians—2 pediatricians and 2 orthopedic surgeons—who selected the few children with the best posture. These children, 12 boys and 12 girls, were called back several days later and personally examined by the committee and the winners picked.

The back of the registration card read as follows: "I hereby give consent for the child named on the reverse side of this card to participate in the Posture Contest and agree to abide by the decision of the Judges." (Signed by parent or guardian.) This was done to eliminate criticism of the fact that the children were photographed stripped.

Silver loving cups were presented to the boy and the girl by a group of local dignitaries as a part of the Tuberculosis Day program, July 28. Each child was sent his photograph together with a chart showing excellent and bad posture and instructions for improving.

The contest was highly commended by all the medical men with whom we discussed it. We intend to give another next spring and should be able to get some interesting results therefrom. We are experimenting with other forms of photography in an attempt to get still better pictures at low cost. We wanted to keep each picture on file, the doctors wanted the pictures for reference and, of course, much of the educational value would have been lost had we not forwarded the pictures to the children, so we decided in favor of the latter. In the next contest we will use some process whereby we can get more than one print and hope to have at least 1,000 entrants.

Mr. Freck will send a copy of the chart given to the children—a letter size mimeographed sheet with 4 illustrations and simple educational material which can be used without a contest.

Important 10 Years Later—In the report of the Cleveland A. P. H. A. meeting—the first session of the newly formed Section on health education we note the following:

Dr. Lee K. Frankel, chairman of the section, in opening the meeting, referred to the need for stressing the positive message, not merely making people understand sickness and its causes, but also the value of health as such.

Where We Hope To Go—Encouraged by searching discussion among Public Health Education Section members at Montreal, Chairman Iago Galdston suggested 5 goals for 1931–1932:

1st: To contribute to the orientation in health education, by which I mean to tie together the numerous independent activities carried on, to help crystallize a policy and viewpoint and an accepted body of technics.

2d: To define better than it is at present defined the relation of our section to the others of the A. P. H. A.

3d: To render our section as useful as possible to health officers, nurses, teachers, sanitary engineers, epidemiologists, etc.

4th: To establish in conjunction with meetings of the A. P. H. A., an institute on health education.

5th: To help in arranging for the 1932 meeting of the A. P. H. A., a meaty and interesting program.

At Montreal But Not Members—

A lot of people in our Montreal sessions are not members of the Public Health Education Section. We need them. We believe they need us. Please check up on health workers in your city or state—and do something about it.

Since July, 1923—In that month's issue of the JOURNAL was the first "Education and Publicity" department, which has since continued with but two or three issues passed by.

How to Write for the Public—

Recently Dr. E. Stanley Abbot discussed the writing of popular pamphlets informally in a letter to Kathleen Larkin of the National Committee for Mental Hygiene. We quote Dr. Abbot:

Whoever is to write the pamphlets of this series should have

1. A rather vivid mental *picture of the public* to be reached by this particular series and by each particular pamphlet;

2. *Empathy*, imagination, a capacity to visualize the information, misinformation, and ignorance which the particular public will bring to the reading of the pamphlets, and be-

cause of that background, what that particular public not only *can* get, but probably *will* get from the pamphlets;

3. Sufficient *knowledge of facts* of mental hygiene;

4. A *sense of proportion* as between normal and abnormal;

5. A *flair* for writing simply, directly, in terms understanding of the people;

6. *Time* enough (a) to get the *facts* from those who have them, if the writer does not already have them; (b) to *weigh them* as to their mental hygiene value for the public they are intended to help; (c) to *consider beforehand* the probable effect of what the writer has in mind on the public he is writing for; (d) to *write carefully*; to *confer* many times and long times with others who know, concerning *all* these points, so as not to overlook any of the points that need to be kept in mind in writing such a series for a general public.

The general plan of getting out a series of pamphlets for the general public has, I think, almost unlimited *possibilities* for good, and so is well worth keeping at. Its *actualities* will depend upon how well its individual parts are done. I am glad you have come to see that the leading authors are not necessarily the ones to write the pamphlets. They would be if they would give the time, the thought, and the work necessary, but they won't. As you are coming to realize, each pamphlet requires a large amount of all three—time, thought, work—besides a fourth—information. Workers with concrete problems, like the teachers, have much information, and some among them are willing to give time, thought and work. But information in other fields which border theirs, and a broader outlook than they are likely to have, are also needed. That broader outlook *you* will have to have—you may have it yourself or may add to what you have by getting it partly from one person, partly from another, thus gradually building it up. I am only trying to give you my little bit to add to what you have. This broader outlook you can then contribute to these coöperators with you in the general plan. It takes time to get it over to them. But when got over, it will be worth much to them as well as to you for the pamphlet series.

All your coöperators have a great deal to learn. We all have. This is one of the troubles. We don't know as much as we need to know in order to write these pamphlets. So don't get discouraged if it takes time, and time, and time to get out even one pamphlet! To get out a really good one is worth it.

BOOKS AND REPORTS

Principles of Sewage Disposal—Bulletin No. 12—*Division of Municipal and Industrial Research, Massachusetts Institute of Technology, Cambridge, Mass.*

This is an 8-page booklet giving the principles of sewage disposal, starting with the necessity of sewage disposal, the classes of sewage, including industrial wastes, and the purposes of sewage treatment processes. The necessity of sterilization of effluent is covered and the extent of sewage treatment required is discussed.

An outline of sewage disposal processes discusses: (1) preliminary methods (screens, grit chambers, plain sedimentation and chemical precipitation); (2) intermediate steps (single-story septic tanks and Imhoff tanks); (3) final treatment (broad irrigation, intermittent sand filtration, contact filtration, trickling filtration, and activated sludge).

The adaptation of the several methods and the question of ultimate disposition of sewage or sewage effluent are briefly covered.

VINCENT B. LAMOUREUX

Tenth Annual Report of Ohio Conference on Water Purification, Columbus, O., October 14-15, 1930.

The tenth annual report of the Ohio Conference on Water Purification is prepared in its usual style so helpful to the busy reader in that short abstracts of the main papers are included in the front. Round table discussions of plant problems covered many phases of activity, including difficulties encountered due to clogging strainers and intakes, reduction of waste by metering and leakage surveys and descriptions of how to make blueprints of reports and a rain gauge. The longer papers range from talks on water softening, iron removal,

lime as a purification agent, use of ammonia-chlorine process, to suggestions regarding laboratory procedure and media.

ARTHUR P. MILLER

Preventive Management: Mental Hygiene in Industry—*Edited by Henry B. Elkind, M.D. New York: B. C. Forbes Pub. Co., 1931. 234 pp. Price, \$3.00.*

This medium sized volume in large easy reading print is made up of a number of chapters by certain well known writers in the field of industrial psychology and relations, and is an adaptation of a course of eight lectures conducted in the spring of 1930 under the auspices of the Massachusetts State Department of Education in cooperation with the Massachusetts Society for Mental Hygiene. The various authors and their contributions are: Meyer Bloomfield, lawyer, "The Next Step in Industrial Relations"; Ordway Tead, industrial consultant and editor, "Human Nature and Management"; V. V. Anderson, M.D., "Psychiatry in Industry"; Henry B. Elkind, M.D., "Practical Applications of Mental Hygiene in Industry"; Harlow S. Person, author and director of the Taylor Society, "Mental Pitfalls of Leadership"; Karl M. Bowman, M.D., "The Industrial Aspects of Morbid Emotion and Fatigue"; Abraham Myerson, M.D., "Fear and Nervous Energy"; and Elliott Dunlap Smith, lawyer, "The Minor Executive and Mental Hygiene"; with a foreword by Henry P. Kendall, President of the Kendall Company, Boston. While so many writers have stated their respective viewpoints upon a more or less common problem, there is, in fact, very little overlapping.

A unique feature which the reviewer considers quite commendable is the

matter of prefacing each article with a page write-up of its author and his principal achievements, from which the reader can certainly derive a better grasp of the respective viewpoint.

The general theme is that wherever human affairs have been organized to accord completely with the idea that prevention is better than cure, progress has been made. The essence of scientific management may be regarded as an attitude, not simply a performance, and involves both the working man and the management for its success.

The discussion is aimed to be on a non-technical level from which it may appeal not only to the technician and expert in industry, but also to the average executive and foreman. A commensurate bibliography of several pages devoted to articles and books which have appeared in the field within the last 10 years is added as an appendix, while there is also a fitting index.

The symposium makes interesting reading without the verbosity which commonly accompanies many articles in mental hygiene and may be regarded as an exemplary presentation of current thought upon an important subject.

E. R. HAYHURST

Occupation and Health—*An Encyclopaedia of Hygiene, Pathology and Social Welfare*—Published by the International Labour Office, Geneva. Distributed in the United States by the World Peace Foundation, 40 Mt. Vernon St., Boston. (2 vols.) Vol. I, 1000 pp. 181 ill. A-H. Price, \$12.00 per vol.

This encyclopaedia of industrial hygiene has a useful place in the office of every industrial health or medical service, and in the office of every city and state health department which is concerned with problems of industrial hygiene. The first volume is now ready. It is the work of about one hundred of the best known experts in the field of

industrial health. Its statements are concise and expressed in as simple a form as is consistent with scientific accuracy. It deals with three main groups of questions: (1) the work, (2) the worker, (3) the environment.

An illustration of the types of subjects treated may be seen in the following brief section from the table of contents: Acids, Acridine, Acrolein, Actinomycosis, Agricultural labourers, Air. It will be seen that topics include harmful substances, diseases, occupations and harmful conditions of the environment. Each cause of disease is discussed on a uniform plan including the following sub-divisions: Chemistry or biology, Sources of poisoning or infection, Uses of the dangerous product, Mode of action, Statistics, Symptoms, Diagnosis, Method of detection in the environment of the individual, Legislation, Bibliography. The occupational diseases are treated in an equally logical manner, as are also the various environmental conditions.

This document is the most complete and reliable reference work of its type.

C. E. TURNER

Principles and Practices in Health Education—*Report of the Sixth Health Education Conference, American Child Health Association at Sayville, Long Island, June 16-21, 1930.* New York: American Child Health Assn., 1931. 485 pp. Price, \$1.50.

Reporting, almost verbatim, a week's discussion of problems in health education, the American Child Health Association has given educators a most useful volume for reference and teacher preparation. This 1930 Sayville conference, as well as the preceding and similar five, has been generously participated in by specialists. With stenotypist accuracy, the spontaneity of their extemporaneous remarks as well as the firmness of their prepared work is retained and made available. Through

intelligent editing the substance of each contribution is retained intact so that the reader catches the intimacy of the sessions without the mind wanderings so generally observed in stenotypist accounts.

Expressing the theme of the conference as a search for basic principles for health education, Dr. W. H. Kilpatrick presents one of his inimitable philosophical treatises outlining the traditional, the scientific, and the dynamic approaches to teaching. Through his statements that "life is a compound of recurring and unpredictable elements," he gives philosophical foundation for suggestions appearing later in the report relative to dynamic curriculums based upon personal problems. This paper of Kilpatrick's with those of Dr. P. M. Symonds on the Psychology of Learning, Drs. Ned Dearborn and Charles Russell on Teacher Preparation, and Dr. T. D. Wood on the Essentials of a School Health Program, alone, makes the volume important.

The enormous number of contributor-specialists makes it impossible to review each. To suggest outstanding sections is difficult because of the divergence of material and general excellence of the comments. One reads, for example, concrete plans for curriculum construction cited by Principal Manley of Springfield, Mo., County Supervisor Nettie Brogdon of North Carolina, Extension Director Maud Brown of Iowa, and Health Education Director Schmoyer of Lynn, Mass., Dr. C. L. Brownell on Physical Education, H. J. Stack on Objectives in Safety, M. A. Bigelow on health conduct and interdepartmental administration, Haven Emerson on health service, Anne Whitney on integration of instruction, Raymond Franzen on evaluating outcomes, and Joy Morgan on progress in health education.

The book is conveniently divided into chapters according to the conference

sections. At the end a summary chapter on high points, lacking only the concreteness such as will eventually emerge from health education discussions of this kind, presents the principles arrived at during the deliberations.

The volume is encyclopedic and will indispensably supplement modern books on specific phases of health education.

D. OBERTEUFFER

Manual of Tuberculosis for Nurses
—By E. Ashworth Underwood,
D.P.H. New York: Wood, 1931.
272 pp. Price, \$2.50.

In the author's own words, "the aim of this manual is to provide, in convenient form, the information which is likely to be required by nurses who are engaged in the hospital management of tuberculosis cases, and also to meet the needs of those who are preparing for the final examination for such qualifications"—i.e., the qualifications for the Certificate of the Tuberculosis Association. Because of the particular purpose for which the book was written, the procedures therein are restricted to local methods and conditions and would be, no doubt, seriously questioned in other countries. Therefore it cannot be used as a guide for nurses generally.

This is to be regretted, for there are few sources of information about tuberculosis which give as complete and yet as simple, logical and clear explanations of terms, progress of the disease, treatments and procedures. It is perfectly clear to anyone, nurse or lay person, the reason for each statement the author makes, because of the unusually logical development of each topic.

The social phases of tuberculosis are well explained. If the author had spent less time upon elementary nursing procedures, such as how to take a temperature and give a bed bath, and had given more definite instructions regarding concurrent disinfection and home care, the book would be more valuable for nurses

called upon to give care to the tuberculous in their homes.

It is to be hoped that the part pertaining to procedures and treatments may be made to apply more generally, for then the book would be a great aid to both private and public health nurses. The paragraph headings, indexed as they are, make for ready reference. The summaries at the end of the chapters are mines of information. The book is well printed, easy to read and nicely bound.

VIRGINIA A. JONES

Accidental Injuries. The Medico-Legal Aspects of Workmen's Compensation and Public Liability—By Henry H. Kessler, M.D. Philadelphia: Lea and Febiger, 1931. 718 pp. Price, \$10.00.

The intensively busy manufacturing State of New Jersey including its great chemical industries has provided the author a rich field for 11 years' experience as medical director of the state's rehabilitation clinic, the first one in the country, coupled with his former capacity as medical adviser of the compensation bureau.

The present work is based on an experience of more than 63,000 cases personally examined and a close following of foreign experience, especially as described by that of L. Imbert. It stands unique among American texts and may be expected to fill a decided want for physicians, lawyers, employers, insurance companies and industrial accident boards and commissions for guidance as conceived by an orthopedic surgeon and industrial hygienist who is constantly dealing with the medico legal features of accident and disease cases. The Foreword is by the well known surgeon, Dr. Fred H. Albee, Chairman of the New Jersey Commission on Rehabilitation.

The first 7 chapters comprise an historical review, the medical aspects of

workmen's compensation laws, the basis of scheduling injuries, the general pathology and end-results of trauma, and the criterions of temporary and permanent disability. The next 10 chapters are devoted to trauma of various parts of the body with pertinent anatomico-physiological discussions and evaluations, usually in percentage, of damage and disability suffered. Chapter XVII on Injury and Disease deals in a masterly way with this most controversial topic and is followed by a short chapter on Traumatic Neuroses. Disturbance of function is recognized as the key to compensation and attempted rehabilitation.

Hygienists will be particularly interested in Chapter XIX, which devotes 124 pages to occupational diseases, stressing the medico legal aspects of foreign and domestic legislation with tables of schedules, matters of arbitration, the fixing of responsibility and the evaluation of disability. Some 28 pages, devoted to lead poisoning, present summaries of 213 cases in the author's series but also extensive inclusions from others, much of which is in classified and tabular form. There follow commensurate discussions of the other common industrial poisons, anthrax, radium, the dermatoses and silicosis. The final chapter is devoted to rehabilitation of the physically handicapped.

The work is essentially the author's own, who writes as one thoroughly versed in his subject and widely experienced in practice. Extensive bibliographies are appended throughout for those who would seek further. Numerous fine half-tone figures illumine the text. Tables, court decisions and case citations abound.

Health conservationists will be interested in the author's plea for a public negligence law to provide compensation for non-industrial accidents and other disabilities suffered indirectly as the re-

BOOKS AND REPORTS

sult of modern congestion, speed of activity, and a chemico-mechanistic existence.

EMERY R. HAYHURST

Asthma and Hay Fever in Theory and Practice—By Arthur F. Coca, Matthew Walzer, and August A. Thommen. Springfield: Charles C. Thomas, 1931. Price, \$8.50.

The authors have thought it necessary to explain the publication of another book on the general subject of allergic diseases, since several have appeared within the last year. There can be no question that specialists and general practitioners alike are coming to recognize the importance of allergic phenomena, not only as seen in special diseases, but also following the administration of the many biological preparations which are now so widely employed in the practice of medicine. We feel that there is no need for the explanation of the authors, since all authoritative knowledge on the subject will be welcomed.

Recognizing that any one man would find extreme difficulty in covering such a subject thoroughly, the book has been written by three authors, all attached to the same school: Part I: Hypersensitiveness, Anaphylaxis, Allergy, by Arthur F. Coca, M.D.; Part II: Asthma, by Matthew Walzer, M.D.; Part III: Hay Fever, by August A. Thommen, M.D. Chapter XVII is the combined effort of Walzer and Thommen, while Katherine Bowman is the joint author of Chapter XVIII.

A work of this sort does not lend itself readily to a detailed review. Each part is introduced by an historical section and followed by an excellent bibliography. The book is concluded with a good general index and a special index of Atopens and Excitants.

In general it may be said that each author has covered his subject in an authoritative manner, which leaves little or nothing to be desired as far as

our present knowledge goes. The third part is especially well illustrated with photographs of trees, grasses, weeds, and their pollens. Even if one has a reasonable familiarity with the general subject, he will be astonished at the great number of excitants to which certain people are sensitive.

The book is well printed, although there are some typographical errors. Unfortunately, heavy paper has been used. It can be commended as one of the most complete treatises on the subject, and the names of the authors insure the accuracy of its statements.

M. P. RAVENEL

Population Problems—By Warren S. Thompson, Director of Scripps Foundation for Research in Population Problems, Miami University. New York: McGraw-Hill, 1930. Price, \$3.75.

The first book is written largely from the standpoint of economics and sociology. Public health as such is not considered, though one chapter is devoted to Famine and Disease as Factors in Population Growth. A number of other important matters which affect public health are treated from the same aspect, such as the relation of overpopulation to unemployment, the teaching of the churches based on the biblical injunction to "be fruitful and multiply, and replenish the earth," and the action of states which encourage the increase in population on account of military power.

The author correctly holds that those who raise families are penalized economically, and believes it is high time to consider the "compensation of mothers as mothers."

The effect of the feeble-minded on the population is well treated under the chapter devoted to The Problem of Quality. Other subjects of interest are: make-up of population, future growth in the United States, world-wide trends,

the effects of migration, emigration, and immigration.

The book is well balanced, but we wish to commend particularly the chapter on The Negro in the United States, which strikes us as being an unusually sane presentation of a vexed question.

The book is written in a very attractive manner. It contains a great deal of history, and each chapter is full of interest. The printing and binding are excellent. There are a good bibliography and an index. M. P. RAVENEL

International Studies on the Relation between the Private and Official Practice of Medicine with special reference to the Prevention of Disease—By Sir Arthur Newsholme. Vol. II. Baltimore: Williams & Wilkins, 1931. 249 pp. Price, \$4.00.

The second volume of Sir Arthur Newsholme's *International Studies*, conducted for the Milbank Memorial Fund, follows closely upon the first (see September JOURNAL, page 1076). It deals with a group of countries whose programs are less helpful as potential guides for American progress but which are essential to the general picture of European experience.

In Belgium, the bulk of health work of the more progressive types is carried by voluntary organizations for infant welfare, and the control of tuberculosis and venereal disease, which are somewhat unfortunately split up along racial and religious lines. Sir Arthur highly commends the program for the control of alcoholism and the scientific application of medicine in the field of penology. Sickness insurance is at present voluntary but likely to be made compulsory by impending legislation.

In the next two nations represented, France and Italy, we find a high degree of governmental and social centralization and relative backwardness in the development of health and social serv-

ices. France has very recently enacted a law providing for sickness insurance, while Italy has not as yet done so except for tuberculosis. In both countries the highly centralized system of government has proved a serious block to local health progress, and in France the reactionary attitude of the powerful medical trades unions has proved an even more serious obstacle. The insistence of the medical syndicates upon the control of dispensary patients by the family physician and upon professional secrecy in its extremest form has made not only public health progress but even the collection of adequate vital statistics exceedingly difficult. The medical profession has endorsed the new sickness insurance act by a vote of 8 to 1, but insists on payment for services rendered and not on a capitation basis. The brightest spot in the picture is the work of the Office d'Hygiene Sociale in the fields of tuberculosis, venereal disease and child welfare.

In discussing Italy, Sir Arthur points out the difficulties due to extreme centralization, all provincial health officers being appointed from Rome and local health work being very elementary except in the large cities. He rightly elaborates on the splendid work done in Milan, which has one of the finest systems of school medical inspection in the world, and has reduced its general death rate from 32.8 in 1878 to 12.5 in 1927. A fuller consideration might well have been given to the splendid work done in recent years in the control of malaria throughout Italy.

Hungary is a country seriously hampered by economic stringency and a somewhat cumbersome governmental system. The outstanding achievements are the magnificent Hygienic Institute of Bela Johan and the work done for maternal and infant welfare by the Stefania Society (a voluntary organization with considerable government subsidies). The tuberculosis death rate

BOOKS AND REPORTS

was still 260 per 10,000 in 1925. Private medical practice has almost disappeared and doctors are woefully underpaid, as a result rather of the general economic condition than of faults in the National Insurance Act.

Czechoslovakia, Yugoslavia and Poland give us the picture of nations created since the war with comprehensive and modern systems of public health and social insurance but hampered in many ways by economic limitations. Sickness insurance in all is compulsory, and treatment is largely carried on in clinics with little free choice of doctors in Czechoslovakia and Yugoslavia, and too much "wandering" from doctor to doctor in Poland. The Czechoslovakia program is particularly notable for the successful coördination of voluntary health activities under a National Council of Social Hygiene.

In Poland the School of Hygiene and the central Nursing School in Warsaw are outstanding beacons of progress and local health centers are being developed throughout the country with marked success.

In Yugoslavia there is a somewhat similar program, Hygienic Institutes at 9 provincial centers, smaller health institutes (80), and still smaller village stations (500). The latter are of a very primitive character, providing chiefly for bathing facilities and medical care rather than public health work in our sense; but the effort to bring the fundamentals of modern sanitation and medicine to all parts of so primitive a country is one of the boldest and finest ever made in any country. Sir Arthur deals only with the work in Croatia. If he had seen it under the vastly more difficult conditions of the Macedonian mountains, his admiration would have been even greater.

It is a source of legitimate pride to America that in the work of the Office of Social Hygiene in Paris, the anti-malaria work of Italy, the Hygienic Insti-

tutes and health centers of Czechoslovakia, Hungary, Yugoslavia and Poland, the aid of the Rockefeller Foundation has played an important part.
C.-E. A. WINSLOW

Essays on Population—By James A. Field. Edited by Helen Fisher Hohman. Chicago: University of Chicago Press, 1931. Price, \$3.50.

This volume is as it were a memorial to the author, who died in 1927. Like the book, *Population Problems*, by Thompson, it also is written from the economical and sociological standpoints and contains much very interesting history. It is made up of a series of essays, the longest of which is on the Malthusian Controversy in England.

Some of the essays have been compiled by the editor from manuscript notes, and some reprinted. The book is well written and extremely interesting, though some of the essays date back as far as 1906; and others, though of later date, such as those on eugenics and birth control, do not take cognizance of the progress which the world has made since they were written.

There is a Foreword by James Bonar, LL.D., and an Editor's Preface, followed by a biographical sketch of the author. The printing and make-up are excellent.

M. P. RAVENEL

Proceedings Fifth Annual Conference, Maryland-Delaware Water and Sewerage Association, Wilmington, Del., May 5-6, 1931.

The proceedings of the fifth annual Conference of the Maryland-Delaware Water and Sewerage Association dealt with the water supply problems confronting the municipalities of these two states. The water supply of Wilmington, Del., was discussed in three papers, one on the pollution of Brandywine Creek by Willem Rudolfs, and others on the history of the supply and new dam

construction. Other papers included filter plant problems, small town water works, odor and taste control, and regional planning.

Two very important papers discussed the troubles in Maryland created by the

drought of 1930, watershed cover and water conservation. The question box covered a number of problems on water works and sewerage construction and plant operation.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Preventive Medicine—A stimulating discussion of the interrelationships between public health and preventive medicine in private practice, and the opportunity of the county unit to foster sound health administration.

ARMSTRONG, D. B. Adequate County Health Organization, Tuberculosis Control and the Medical Profession. *New England J. Med.*, 205, 12: 569 (Sept. 17), 1931.

Tuberculosis in the Rural South—Although tuberculosis is definitely lower in children of southern rural districts than in a typical northern city, the increase of infection with age is similar in trend. Of colored children 60 per cent reacted, whereas only 51 per cent of the white children from 5 to 9 gave evidence of infection.

ARONSON, J. D. Incidence of Tuberculous Infection in Some Communities of the South. *Am. J. Hyg.*, 14, 2: 374 (Sept.), 1931.

Public Health Pioneering—British opinion commending the trial of new hygienic projects by local authorities in a country where health administration is much more standardized than in our own.

BUCHANAN, G. Some Recent Policies Regarding Particular Diseases. *Brit. M. J.*, 3684: 283 (Aug. 15), 1931.

Coal Mining and Tuberculosis—Though the coal miner has a relatively low death rate from tuberculosis, the death rates (in Great Britain) from bronchitis are high. The discussion of the phenomenon has much of value to American sanitarians.

CUMMINS, S. L. Coal Miners and Tuberculosis. *J. State Med.*, 39, 9: 526 (Sept.), 1931.

Finding Childhood Tuberculosis—Opportunities open to the public health

nurse are suggested in this clear account of diagnostic measures.

EDWARDS, H. R. Tuberculosis in Children. *Pub. Health Nurse*, 23, 9: 402 (Sept.), 1931.

When Death Rates Go Up—This absorbing dissertation on the real meaning of death and birth rates and population figures, intended for the intelligent layman, has plenty of meat for the viewers-with-pride among our ebullient statisticians.

FAIRCHILD, H. P. When Our Death Rates Go Up. *Survey Graphic*, 66, 11: 510 (Sept.), 1931.

Tuberculosis in Tennessee—Chief among the features of this program are case-finding clinics, consultant service, nursing follow-up, and study of hospital needs. The first is discussed in detail. A program that would be applicable to most states it would seem.

GASS, R. S., and BISHOP, E. L. Tuberculosis Control in Tennessee. *J. A. M. A.*, 97, 12: 843 (Sept. 14), 1931.

Experimental Epidemiology—Another demonstration of herd reaction to infection by Greenwood's mice.

GREENWOOD, M. Factors Determining the Difference Between an Epidemic of One Disease and that of Another. *Brit. M. J.*, 3683: 231 (Aug. 8), 1931.

In the Cause of Health Education—Reasons why physicians ought to use their influence toward improving the health courses in public schools.

Ivy, A. C. A Deficiency in Present Day Education. *J. A. M. A.*, 97, 9: 588 (Aug. 29), 1931.

Medical Societies and Public Health—Pleading for more efficient participation in public health administration by county medical societies, the author makes some bald statements that

might be challenged, but the value of the proposal is not to be doubted.

McLAUGHLIN, A. J. The Medical Profession and the Public Health. *Pub. Health Rep.*, 46, 35: 2041 (Aug. 28), 1931.

A County Health Survey—Recommendations for improved service based upon this survey of a southern county health department would apply to most administrative units, large or small.

MOUNTAIN, J. W. Public Health Service in Knox County, Tenn. *Pub. Health Rep.*, 46, 34: 1981 (Aug. 21), 1931.

Community Public Health Nursing—A complete answer to the question: what is public health nursing? The problems of community organization are given a thorough airing.

NELSON, S. C. How Public Health Nursing Can Best Serve the Community. *Mod. Hosp.*, 37, 3: 128 (Sept.), 1931.

About Tuberculosis Prevention—In this progress report of the Massachusetts 10-year plan are many practical conclusions. A definite relation exists between the adult tuberculosis death rate, per cent of child reactors and cases of tuberculosis in school children. Exposure in the home is the most potent factor in producing childhood infection. There is much more.

POPE, A. S. The Discovery and Prevention of Tuberculosis in the Community. *J. A. M. A.*, 97, 12: 846 (Sept. 19), 1931.

Further Experience with BCG Vaccine—From Canada comes more evidence in support of the immunizing value of BCG vaccine.

RANKIN, A. C. BCG Vaccine. *Canad. Pub. Health J.*, 22, 9: 459 (Sept.), 1931.

British Views on Sex Education—Excellent indeed is this presentation of the need for better sex education by a British churchman addressing an annual meeting of the British Medical Association. Imagine the A. M. A. including

this subject from such an ecclesiastic source.

PYM, T. W. The Need of Education in Questions of Sex. *Brit. M. J.*, 3682: 186 (Aug. 1), 1931.

Anti-Vivisection Answers—Another well-thought out, logical, and eminently sound statement refuting the mouthings of the anti-vivisectionists. Useful reference material.

REED, C. I. Animal Experimentation. *Ill. Health Quarterly*, 3, 3: 204 (July-Sept.), 1931.

Vision Conservation—What nurses should know about eyesight conservation is told in this symposium, and this information should be a part of the equipment of other health workers.

ROYER, B. F., *et al.* High Lights on the Conservation of Vision. *Am. J. Nurs.*, 31, 9: 1077 (Sept.), 1931.

Research in Public Health—Recounting the progress and methods of research carried on by the Chicago Department of Health through its laboratories.

TONNEY, F. O. Success in Public Health Research. *J. A. M. A.*, 97, 10: 700 (Sept. 5), 1931.

Health Education in Rural Schools—A straightforward account of a job well done under primitive conditions and with only the tools at hand.

WOODBURY, M. C. Health Education in the One-Room School. *Pub. Health Nurse*, 23, 9: 415 (Sept.), 1931.

More Tuberculosis Case-Finding Research—Further findings of the important 10-year program in Massachusetts. One school child in a thousand is found with adult type tuberculosis; a quarter of these are dead after five years. The implications of the whole findings are discussed.

ZACKS, D. What We Have Learned in Massachusetts from the Ten-Year Program. *New England J. Med.*, 205, 11: 525 (Sept. 10), 1931.

NEWS FROM THE FIELD

THE 300,000TH LEITZ MICROSCOPE
THE Optical Works of E. Leitz, in Wetzlar, Germany, have completed their 300,000th microscope. This instrument was presented at an appropriate gathering to Geheimrat Professor Dr. Ludwig Aschoff, of Freiburg, in Breisgau, Germany, a scientist and physician of world renown in the pathological and anatomical field of scientific endeavor.

The dedication of this microscope follows a custom of the firm of E. Leitz to present every 50,000th microscope to an outstanding scientist or institute, thus expressing their appreciation of the co-operation extended by leading authorities to the Leitz Works.

The 100,000th microscope was presented to Dr. Robert Koch, of Berlin, and the 150,000th to Dr. Paul Ehrlich, of Frankfurt.

DRUG CONTROL POLICY UNCHANGED
THERE will be no changes in the policy of the Food and Drug Administration of the U. S. Department of Agriculture pertaining to enforcing the present drug control law, says Dr. F. J. Cullen, the newly appointed chief of drug control.

"Inquiries as to possible changes in drug control policy in enforcing the law have been received, and I take this occasion to state that it is the purpose of the administration, in its regulatory work with drugs and medicinal preparations, to continue vigorously its program of action under the food and drugs act against medicinal preparations falsely and fraudulently represented by label or circular accompanying the package as preventives or treatments for disease conditions."

CHILD HEALTH CONFERENCE ORGANIZED
A COMMISSION of 16 members to study the problems of child health and protection in Iowa was appointed June 9 by Governor Turner. Two conferences have already been held, section and subcommittee chairmen appointed, and plans made to study the entire field of child welfare work in the state and to work out plans for coördination and more efficient operation of the various projects and activities.

MISSOURI DROUGHT AREA RELIEF
THE drought area of Missouri has been divided into 5 districts of 9 counties each, for the administration of the state's share of the \$2,000,000 appropriated by Congress for the U. S. Public Health Service in drought areas. Each district will have a physician, a sanitary engineer, a laboratory technician and 5 nurses.

NEW LEGISLATION IN SWEDEN ON MATERNITY BENEFITS

A ROYAL decree of June 26, 1931, makes provision for the first time in Sweden for the payment of maternity benefits from the national treasury to women, whether married or single, who do not belong to sickness insurance funds and whose income, whether singly or together with that of their husband, is below a certain amount.

The benefit of one krona (26.80 cents) a day is paid for 30 days on the condition that the woman abstain from employment; women who are protected by the labor law and who are by that law required to stay away from work for at least 6 weeks may receive the benefit for 56 days.

The benefits are paid on application to the sickness insurance funds. Each applicant is sent information on the proper care of herself and the child. Midwives' services or hospital care may be provided on request, but a deduction is made from the maternity benefits for such services.

This decree is to become effective by a special proclamation of the King.—*Svenska Författningssamling*, Stockholm, No. 279 (July 4), 1931.

MUTUAL AID FUNDS FOR SCHOOL CHILDREN IN ITALY

A SYSTEM of mutual aid societies was instituted in the Italian schools a few years ago. The societies are under the supervision of a national organization. Their object is to provide medical aid and country vacations for school children and to take measures for preventing sickness and for promoting knowledge of legislation relating to health and social welfare. The money for their support is contributed by the National Social Insurance Fund. Membership is optional for children in the schools, and each child who joins pays an annual fee of about 5 lire (26 cents). This money is saved and when the child reaches the age of 20, it is transferred to his credit in the fund for invalidity and old-age insurance, which is compulsory in Italy for a large majority of the workers; if he is not subject to insurance, it is credited to his account in a savings bank.—*La Stirpe*, Rome, Apr., 1931.

FRENCH DENTAL CLINIC FOR SCHOOL CHILDREN

A DENTAL clinic for school children will be established in the city of Paris. The cost of construction will be covered by a gift from an American philanthropist; the expense of maintaining the clinic will be supplied by the city. This will be the first institution of its kind in Paris; heretofore only

10,000 out of the 250,000 school children were given free treatment in the hospitals and schools of dentistry. Under the new system children will have their teeth examined 3 or 4 times a year and will be sent for treatment to the new clinic.—*Revue Internationale de l'Enfant*, Geneva, Apr., 1931, p. 409.

NATIONAL CHILD WELFARE BUREAU, COSTA RICA

A COSTA RICA law of August 15, 1930, provides for the establishment of a governmental bureau for child welfare work (Patronato Nacional de la Infancia). Emphasis is placed on the protection of the child's health and on watching the conditions of his mental, moral, and social life. Work for the prevention of maternal and child mortality and for the prevention of disease is also among the functions of the bureau. The bureau will prepare plans for the establishment of health resorts, playgrounds, hospitals, and other institutions for children; it will also supply information and advice on child welfare matters and watch over the enforcement of the child welfare laws. A special section enumerates in detail the various subjects which the bureau is expected to study.—*Boletín del Patronato Nacional de la Infancia*, San José, Costa Rica, 1, 1, 1930.

CHILD WELFARE CONGRESS

THE first National Child Welfare Congress of Costa Rica was held in the capital, San José, April 26–May 3, 1931, under the auspices of the recently established National Children's Bureau, which is a branch of the National Government.

A number of papers were presented dealing with various phases of child welfare, for instance, infant mortality, health of mothers and children, school attendance, physical education of school children, and juvenile delinquency.

Many resolutions were passed on the

above subjects. The Congress has asked the government to appoint a committee for drafting bills on juvenile courts, child labor, adoption, children of illegitimate birth, marriage and divorce, and to introduce these bills into the National Legislature in 1932.—*La Gaceta*—*Diario Oficial*, San José, Costa Rica, May 24 and June 19, 1931.

LEAGUE CALENDARS FOR 1932

AN unusually artistic wall calendar is being offered by the Publications Committee of the National League of Nursing Education, 450 Seventh Avenue, New York, N. Y. Also for the first time the committee is presenting a practical desk pad and calendar.

The wall calendar has some charming pictures of many of the Saints from the history of nursing. The frontispiece is Giotto's famous old fresco of "St. Francis and the Birds" done in colors. Among the twelve attractive plates which appear in the wall calendar are St. Vincent de Paul, St. Elizabeth of Hungary, St. Catherine of Siena, Sts. Cosimo and Damian, and Fabiola. The price of the "Nursing Saints Calendar" is \$1.00 per single copy, and \$.75 per copy on orders of 50 or more delivered in one shipment.

The desk pad and calendar has a page for each week of the year, with a space for morning and afternoon appointments for each day. That the calendar pad comes from the League is shown by weekly quotations taken from League publications which are as applicable today as when they were written. The engagement pads will be \$.50 each, or \$.40 if ordered in quantities of 25 or more delivered in one shipment.

CANCER BOOKLETS

THE American Society for the Control of Cancer has put out an excellent series of popular booklets for the laity, giving the main facts concerning cancer and the proper method of pro-

cedure. These booklets will be sent to physicians, health officers, as well as to the laity, free of charge, in single copies or in quantities.

The work of this society is too well known to professional men to need comment. We trust that this information will be spread further through the instrumentality of health officers and readers of this JOURNAL.—Address, American Society for the Control of Cancer, 25 West 43d Street, New York, N. Y.

DELTA OMEGA

AT the annual meeting of Delta Omega, the honorary public health society, which was held in the Windsor Hotel, Montreal, Canada, on Monday, Sept. 14, Dr. James A. Tobey of New York was elected national president, succeeding Dr. John A. Ferrell. Professor Charles G. Hyde of the University of California was elected Vice-President, and Professor Ira V. Hiscock of the Yale School of Medicine was re-elected Secretary-Treasurer.

Dr. Mazÿck P. Ravenel of the University of Missouri was elected the ninth national Honorary Member of the society.

The meeting was attended by about 50 members representing the 6 chapters of Delta Omega, located at Johns Hopkins University School of Hygiene, Harvard School of Public Health, Massachusetts Institute of Technology, University of Michigan, Yale School of Medicine, and University of California.

YEAST RESEARCH

MELLON Institute of Industrial Research, Pittsburgh, Pa., has announced that the institution has accepted from the National Grain Yeast Corp., Belleville, N. J., a grant for a comprehensive investigation of the chemistry and technology of yeast. This research, which will be operated as an Industrial Fellowship of the Insti-

tute, will be conducted with the close collaboration of specialists in the donor's organization; and the results will be made available as the various stages of the studies are completed.

PERSONALS

DR. LEWIS H. HOWARD, who has been city Health Officer of Tucson, Ariz., since April 1, has been appointed Health Officer of Pima County, the city and county units being combined. Dr. Howard succeeds Dr. Alvy Nelson Crain, Member A. P. H. A., who resigned to become Health Officer of Maricopa County, with headquarters in Phoenix, Ariz.

DR. ARTHUR HIERONYMUS, Member A. P. H. A., formerly Health Officer for the City of Alameda, Calif., for 20 years, has been appointed Health Officer of the city of Oakland, Calif.

DR. JAMES F. ELDER, Member A. P. H. A., has resigned as health director of Mahoning County, with headquarters at Youngstown, Ohio. He is succeeded by Dr. George Y. Davis. Dr. Elder has been appointed health director of the third district health unit recently organized in the drought area, comprising nine counties, with headquarters at Van Buren, Mo.

DR. JAMES P. MOON, of Tiptonville, Tenn., Health Officer of Lake County, Tenn., has been elected president of the Mississippi Valley Public Health Workers Association, a permanent organization recently formed.

DR. JESSE LYNN MAHAFFEY, of Haddonfield, N. J., has been appointed director of health of New Jersey, to succeed David C. Bowen, whose term expired.

DR. WILLIAM W. BAUER, Member A. P. H. A., Health Officer of Racine, Wis., for the past 8 years, has been reap-

pointed for a term of 4 years. New quarters for the health department will be opened in the city hall in October.

CONFERENCES

November 6, New York State Association of Public Health Laboratories, Albany, N. Y.

November 9-14, the Ninth Texas Sanitarians' Short School, Houston, Tex.

November 10-13, New York State Conference on Social Work, Niagara Falls, N. Y.

July, 1932, The Second International Conference of Social Work, Frankfurt, Germany.

September 6-9, 1932, Annual Meeting of the International Union Against Tuberculosis, The Hague, Holland.

A Suggested Community Mental Hygiene Program*

GEORGE S. STEVENSON, M. D.

Director, Division on Community Clinics, The National Committee for Mental Hygiene, New York, N. Y.

IT might be appropriate to change the title of this presentation so that it would read "Suggestions for a Community Program." I hope that I may be successful in stressing the point that a cut and dried pattern is quite out of order, and obstructive to a community program in health and other social fields. There is altogether too much parroting of that sort. A program that fits beautifully into one community is sometimes copied blindly by another and found seriously wanting; or, what is even worse, a program that works only moderately well is copied with its bad as well as its good features. Similarly, too often the sponsors of a program that works out well in one community conclude that a program which differs is to be condemned, even though the differing program may be in a quite different community.

Perhaps it is to be expected that the psychiatrist who can rely so little on formula and prescription in his work, who finds no two cases alike, and has little patience with bionomial diagnosis, would extend his demand for individual treatment to the community. Individualization is the keynote of this presentation, still it must be common sense individualization, and not the sort practised by the man who rejects the experiences of a community of 40,000 population because his problem has to do with the community of 35,000.

The approach to a bit of community organization has certain features in common with medical practice. The community is a patient;

* Presented at a Joint Session of the Child Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 14, 1931.

it has defects; perhaps it is suffering because it has not sufficient of a health or social program to allow it satisfactorily to digest its school program. The community is a more or less integrated individual, and no one phase of community endeavor is self-sufficient. Each affects the other and all must be considered in the planning of any one. The community may have disorders as well as defects. It may have attempted to assimilate a health program which is so at odds with its individual characteristics that it suffers permanent distress and seeks help perhaps from this or that national organization. The community is also similar to the patient in that we find the technical approach to a problem to be the same. First there is a complaint, then examination, then diagnosis and prognosis, and finally treatment.

With all of these possibilities for the entrance of variables into the situation, is it not clear that a community program cannot be a finished plan? About the only thing that is finished in the community program is the part that has been so tried that its success is evident. Even that is constantly being supplemented. Instead of conceiving of a community program as a set picture, it is probably more productive to think of it as a chain of probable steps looking into the future. Each step has to be scanned thoroughly and reconditioned before it is put into operation. There must be alternate steps and flexibility which will allow of every opportunity for constructive growth. Such a view of a community program predetermines a policy of slow building and continuous integration, and precludes anything in the nature of mimeographed directions.

There is no such thing as an adequate, universal, community program. Only the individual utilization of experience leads to satisfactory provision to meet a community need. In fact, the satisfactory program is a result of three sets of influences: the community need, the community peculiarities, and the accumulated experience of other communities.

COMMUNITY NEEDS

Community needs are the most constant of this triad because they are the outgrowth of the needs of the people composing the community. People do not differ so much from place to place. We find, in general, that 4 phases of mental hygiene service are demanded: The extreme, or custodial phase, is represented by the feeble-minded and psychotic, who cannot be rehabilitated. The remedial is represented by the ambulant, or institutionalized patient, where the major motive is the elimination of a developed condition, which is in itself intolerable. The preventive mental hygiene effort may often appear in many re-

spects remedial, because a problem already exists, yet if the attack on the problem presented is conditioned more by the future threat than the present, intolerability of the disturbance, the motive of prevention, dominates. The fourth phase is that of enrichment, or positive health, wherein the effort is toward the increasing of the efficiency and margin of safety of the individual as to his mental life, and the releasing of his potentialities thereby, for greater constructive effort and greater enjoyment of life. It is obvious that there is no sharp dividing line between these 4 phases. They represent a gradation, all points of which must enter into the conception of a community program.

Community needs may be conveniently looked at from the standpoint of specific services. A mental hygiene program must consider provision for the major and minor psychoses, borderline deviations, and those arising obscurely in association with other medical and social problems. The program that does not at least consider the mental hygiene needs of the person who has "heartburn" and "gas," or who has an undue fondness for other people's property, is apt later to find its community in the category of those complaining of a defect. Provision for the mentally retarded is an essential part of any program, and the need of the problem child has become so far recognized as a community need that today we find the equivalent of 3,000 hours per week of high grade clinic service for children in the United States. Beyond this point the community mental hygiene needs fall to a large extent outside the medical field and require that the erection of a community program consider, and at least leave place for, mental hygiene functions of the school, the court, the social agency, the recreational agency, the church, the home and the workshop.

The essential developments in these fields should if possible antedate the more complicated psychiatric services for children; in fact the National Committee for Mental Hygiene consistently urges that, even where assured, the establishment of a child guidance clinic await such development if there is any reasonable hope of success.

The extent of decentralization that is necessary to insure geographical and functional economy in these various fields must be considered. Is time saved and is coöperation effected from close proximity to the case, with the effort and expense of putting it through, instead of at a central point? How far must strong centralization be insisted on? A community needs both the benefits of centralization and decentralization, and the optional compromise based on individual circumstances is the answer. Such services as night clinics for the employed, and observation facilities, are features which represent a response to a need for all-around economy of service. Many other tricks

of program organization, representing community needs, are revealed in a study of accumulated experience.

COMMUNITY PECULIARITIES

Community peculiarities represent the chief variable in the construction of a program and exact of us this much stressed individual consideration. Unless we know community peculiarities, we have no basis for integrating our accumulated experiences so that they will meet community needs. The survey approach is the chief instrument for bringing community peculiarities into the form of workable data. Such a survey may be made specifically from the mental hygiene viewpoint, or may be part of a broader health or welfare study.

This community examination is, of course, best done by one who is accustomed to making such studies, and for the most part, such persons are associated with, or known to, national agencies. But at times it is necessary to rely on a local or imported person whose authority lies in the technical mental hygiene field, although not experienced in the variables of community organization. Less satisfactory, but still far better than ignorance, is the self-survey, whereby the examination is conducted by inexperienced local talent, if possible, with authoritative direction, maybe from the outside. Such a community examination should reveal peculiarities of size, population, geographical and climatic influences, culture, wealth, social structure, efforts in progress which bear on mental health, and proximity to centers of population, universities, hospitals and other resources. The study should reveal community habits of stability and political attitudes and interferences. Ignorance of these things has been a cause of grief to many a project otherwise well conceived.

ACCUMULATED EXPERIENCE

Given an appreciation of community needs and peculiarities, we look to accumulated experience to guide us to a course of action. Accumulated experience is quite different from isolated experience, the guide which is used when one community copies the plan used by another. Accumulation of experience requires the study of a large number, as many as possible, of programs in action under different conditions and with various degrees of success. It is preferably analytical so that the causes of success and failure are not ignored, and so that a good trick in a poor total job, or a poor element in a total good program, will not pass unnoticed. The accumulation of experience is primarily the job of the national agency, which is most apt to see in one city the very experience that another is looking for. The national

agency is in a position to watch a trend developing, to keep in touch with it, to evaluate it by comparison with other experiences, and to call it to the attention of the community which needs it. If for nothing else than to lay out an itinerary for the accumulation of experience by those locally involved in construction of a mental hygiene program, I feel that the national agency has a contribution to make to every project of this sort. I say this not with the spirit of vaunting, but with the seriousness that comes from seeing the valuable discoveries and precious experience of a program in one place ignored by another.

Reduced to its essentials, the foregoing discussion of the philosophy surrounding the creation of a community program could be stated as follows:

A community program is not a completed picture, but a line of procedure with alternate steps. It must consider all phases of mental health work—custodial, remedial, preventive, and enriching. It must cover the major and minor psychoses, borderline deviations, account for the feeble-minded, and serve the problem child. It must be adapted to the individual community through the reconciliation of community needs, community peculiarities, and accumulated experience. The creation of a community program is a job of individual case procedure.

However, generalized statements about individualizing are not much of a guide or help when it comes to a real situation, unless they can be attached to something. I shall therefore temper this plea for individualization by presenting something concrete, a sort of platform from which to take orderly steps. I have chosen, as my paradigm, the city of 75,000 to 200,000 population. In such a city there is little opportunity for the degree of specialization which exists in larger cities, where there are clinics for adults, court cases, school cases, social agency cases, college students, children, preschool children, retarded children, superior children, and so on. A city of 100,000, in order to get the benefits of clinical and educational work, and the community leadership that comes from an adequately staffed full-time program, must work out a plan including all phases of the job.

Such a community might plan on a budget of \$15,000 to \$20,000 to develop a working unit consisting of a psychiatrist, psychologist and 2 psychiatric social workers, with a schedule laid out to cover the community needs as outlined above. The essentials of this would be: service to adults, which might consume 2 days a week of this unit's time; service to problem children, which might consume another 2 days, and work with the mental defective the fifth day. These sessions might be held at the same place, possibly under different names,

or they might scatter. It might be that the 2 days for children would be divided; that 1 of the days for adults would be devoted to the neuroses and consultations on cases from other medical services. The remaining half day of the week might be devoted to consultation service with a nursing agency, social service agency or juvenile court, or such consultation services might be given in place of part of the time devoted to adults, children, or mentally defective.

A definite part of such a program should be its educational effort, and this should be a consciously planned thing, not merely the result of chance. It should grow out of the needs for such activity as they are revealed by the cases, and should accordingly be directed toward professional and lay groups. Similarly, growing out of the case work should be a responsibility for community improvement so that those stresses which are contributing to the mental hygiene problems may be attacked as a designated part of the job.

Such a program should have a committee or board sufficiently free of other obligations and of sufficient local standing to govern it, insure its interpretation to and integration with the community, and be able to reveal the community to the clinic staff. It should assume full responsibility for financial stability. Such a board might well be an outgrowth of the group which originally studied the community's peculiarities through a survey.

This skeleton of a program for a city of 75,000 to 200,000 should provide a useful point of departure for the city that is either larger or smaller. The city of 200,000 could well afford to specialize to the point of providing a full-time unit for children, and a city twice that size would probably find that besides a community unit, a public school or juvenile court unit would be a logical direction of growth.

The city under 75,000 would have more difficulty because of the necessity for getting part-time personnel. However, there is already justification for considering partnership between smaller cities whereby the benefits of the larger support can be secured. Such partnership may be worked out between a small city and an institution or university. Much of the promise of the future, however, lies in the participation of the state in the program of the small city and rural district. The state hospital is particularly strategic in serving this part of the population which, it must not be forgotten, includes 75 per cent of the whole.

A psychopathic hospital or a university is similarly able to aid a mental hygiene program in the smaller community, and in some instances state departments of health, education and welfare have demonstrated their possible contribution. The construction of a program

for the smaller community requires the reduction to a minimum of makeshift and irregularity, careful attention to follow-up, and the evaluation and utilization to the utmost of local capacity for participation. I hesitate to say much about program planning for the small community for we are just now bringing together the experiences of the states which have experimented along these lines. Two field workers are spending a year and a half studying existing programs to draw therefrom elements that may be of value as accumulated experience.

One of the most valuable beginnings for a community wishing to make a start in a mental health program is the securing of a visiting teacher for the public schools, and I recommend serious consideration of this.

In conclusion, may I again express the hope that any who may have been looking for a formula may, in place of it, achieve a viewpoint that will result in an individually conceived, and therefore more appropriate, plan for mental hygiene service to a community.

Dental Caries

IN an Interim Report, the Medical Research Council has given an answer to the second of two questions which it is considering:

"(b) Can the incidence and rate of progress of caries in teeth already erupted be lessened by the adoption of similar dietetic measures?"

1. In groups of children, numbering from 65 to 86, living under similar institutional conditions, each group receiving a certain specific addition to the standard dietary, over a period of 2 years, the progress of caries in the permanent teeth has been significantly retarded in those children receiving an added ration of fat-soluble vitamins as compared with those whose additions consisted of treacle and olive oil respectively; the increase of caries in the vitamin group, whether measured by its incidence or its extent, being approximately one-third of that in the other groups.

2. In two groups of children, numbering 82 to 79 respectively, living in the same institution under identical conditions, each receiving as an addition to the standard dietary a measured ration of olive oil, to which in the case of one group a solution of vitamin D was added, over a period of 1½ years, the progress of caries in the permanent teeth was also significantly retarded in the vitamin group as compared with the group which received olive oil as the only addition.

3. When allowance is made for the shorter period of the second as compared with the first investigation, a general similarity is observable, in the rate of increase of caries, between the group receiving cod liver oil (vitamins A and D) and that receiving radiostol (vitamin D).

4. There was no significant difference in the rate of increase of caries between the children receiving olive oil and those receiving treacle, in the first investigation.

—*Special Report Series, No. 159*, by the Committee upon Dental Disease, Medical Research Council, 1931.

British Public Health and Its Present Trend*

GEORGE. F. BUCHAN, M. D., M. R. C. P., D. P. H., HON. F. A. P. H. A.

Medical Officer of Health, Willesden, England

IT is difficult to say when public health began, but it is probably as old as communities. The need for communal action for the protection of the public health has no doubt been realized because of the ravages of epidemic disease. It is probably beyond dispute that the Black Death in Britain in the 14th century and the Plague in London in the 17th century have been important influences in the development of British public health.

Public health assumed a definite form in Britain during the 19th century, and it is interesting to note that it has extended with every extension of the franchise. In Britain there have been four great extensions of the franchise, in 1832, 1867, 1884 and 1918. Following the extension of the franchise in 1832 the reform of the Poor Law began in 1834 and reform of Local Government in 1835. These changes were followed by the passing of the first Public Health Act in 1848. The next extension of the franchise in 1867 was followed by the Public Health Act of 1875 which still remains in England as the health charter of the people. The extension of the franchise in 1884 was followed by further reforms of Local Government in 1888 and 1894. These local government reforms created county councils and placed certain definite public health responsibilities on other local authorities, particularly the urban and rural district councils. The last great extension of the franchise was in 1918, when the number of parliamentary voters was practically trebled and for the first time included women. This last act of enfranchisement was followed by the Local Government Act of 1929 which indicates the present trend of public health administration in Britain.

In spite of much legislation during the present century it is nevertheless true that the Public Health Act passed in 1875 is still the most important public health measure on the Statute Book in Britain. This Act deals with environmental hygiene, with the protection of the pub-

* Read before a Special Session of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

lic against unsound food, with infectious diseases and the establishment of infectious diseases hospitals, while it gives to the Minister of Health power to make regulations for the control of infectious diseases. It is under this Act that in recent years health authorities in England have been required to deal with tuberculosis, venereal diseases, ophthalmia neonatorum and puerperal pyrexia. It is also under this Act that local authorities may maintain general or special hospitals. But when all is said and done the Act of 1875 has been mainly used to deal with environmental conditions as they affect health, and with measures for the protection of the public against the spread of infectious diseases.

It was not until the beginning of the present century that a more personal view of public health began to be taken. In 1902 the first Midwives Act was passed. This Act seeks to protect the woman against unskilled attention at confinement. It requires that every woman practising midwifery should be trained and certificated according to a standard laid down.

In 1907 the first Notification of Births Act was passed. This Act has for its object the early notification of births so that advice and help may be given early to mothers on the healthy upbringing of their children. It was at first subject to voluntary adoption by local authorities, which is a common procedure in Britain when a measure is to be tried out. Later in 1915 Parliament made this Act compulsory on all authorities. The next development of personal hygiene was also in 1907, when the Act requiring provision to be made for the medical inspection of school children was passed. This Act while embodying a compulsory provision regarding medical inspection embodied a voluntary provision with regard to treatment. This voluntary provision was subsequently made compulsory in the Education Act of 1918.

In 1911 another important Act dealing with the care of the individual was passed, namely, the National Health Insurance Act. This Act compelled those persons mentioned in the Act—generally speaking, persons with an income of less than £250 per annum—to insure under a State Scheme. Among the benefits conferred under this system of State Insurance was medical benefit, i.e., general practitioner treatment. The National Health Insurance Act can hardly be said to be preventive in character although there are some rarely used provisions in it which have been conceived on a preventive basis. The Act however is of great importance in that an insured person is able to secure treatment immediately he becomes ill without additional expense to himself. This Act was also instrumental in initiating schemes

for dealing with tuberculosis which have since become applicable to the whole community.

In 1918 a further step forward was taken by the State in respect to the care of personal health. In this year the Maternity and Child Welfare Act was passed, enabling local authorities to establish, subject to the approval of the Minister of Health, schemes for the care of expectant and nursing mothers, infants, and young children, and it is under this Act that practically all the maternity and child welfare work in Britain is being carried out.

UNIFICATION OF CENTRAL AND LOCAL AUTHORITIES

It will be readily understood that as these various measures for the protection of the health of the public were being rapidly passed by Parliament, the necessity for some State supervision of their working became more and more apparent. The result was that in 1919 the Ministry of Health was established by Act of Parliament for the purpose of controlling all functions of the State relative to public health and the State practice of medicine, whether preventive or curative. With this concentration of the medical and public health functions of the State in a single Central Health Department, the need for concentrating the public health functions of local authorities in a single local authority for each area became equally apparent. Toward this end the Local Government Act of 1929 has taken a step. This Act abolishes boards of guardians under which the Poor Law system of medicine has developed in Britain, and transfers all the functions of boards of guardians to county boroughs and county councils. This transference has been made in order that county boroughs and county councils at a later date may incorporate the old Poor Law system of medicine with the public health system of medicine in operation in their areas. This Act came into operation in 1930, and it doubtless will have a very important bearing on public health progress in Britain.

THE LOCAL GOVERNMENT ACT, 1929

The main provisions of the Act may be conveniently discussed under four headings:

1. *To Improve Local Government*—The Act seeks to establish that local governing authorities shall be large enough to look after themselves. The Act also enables steps to be taken by which in the long run there may be only one local health authority in any area and not two or three as at present. This ultimate issue will depend largely on the wisdom and vision of the county councils entrusted with very large powers under the Act. The Act if well administered should pave the way for the general establishment of county borough health administration throughout Britain. The county boroughs vary in population from about 25,000 to over

BRITISH PUBLIC HEALTH

1,000,000, and the county borough council in each of these areas is required to administer all local public health services. In Scotland but not in England this includes mental health. This reduction in the number of local health authorities and unification of their powers should make for a rapid extension of public health work.

2. *To Extend and Improve Hospital Accommodation*—In connection with any extension of public health work the importance of the hospital is becoming more and more apparent. If a local authority decides to establish a clinic for the early diagnosis and treatment of cancer, hospital beds are necessary. Similarly, if it decides that the rheumatic child should have attention, beds are again necessary. Like statements may be made about all the most recent advances in public health administration. It would therefore appear that for the proper development of public health work easy access to hospital beds is essential.

Prior to the operation of this Act there were in England and Wales the voluntary general and special hospitals with 50,000 beds, which still remain as such; the Poor Law general hospitals with 120,000 beds, which have now been transferred to county boroughs and county councils and have become the municipal general and county council general hospitals; and the special hospitals of local authorities for tuberculosis, infectious diseases, maternity, and so forth, with 60,000 beds. It will therefore be observed that there now exist in England and Wales 50,000 voluntary hospital beds under voluntary management and 180,000 municipal or county council hospital beds under public management.

It is provided in the Local Government Act, 1929, that extension of any of these hospitals in any area should take place only after consultation between the voluntary and public managers of hospitals in the area. Hitherto the voluntary hospitals have been the teaching hospitals and I am hopeful that the coöperation between hospitals which the Act seeks to secure, will lead to a greater utilization of the public hospitals for teaching purposes. Such a result would be in every way beneficial. It would provide more material for the student and particularly would tend to uplift and improve the personnel of the staff of the public hospital.

3. *To Make Public Health Available for the Whole Community Irrespective of Poverty*—This has been done by abolishing boards of guardians who previously administered Poor Law medical work and transferring their duties to the public health authorities. This transference of duties includes vaccination, domiciliary medical attendance for persons in receipt of Poor Law relief, and the maintenance of Poor Law hospitals. The public health authorities are further enabled to declare that all assistance provided by them is provided otherwise than by way of poor relief.

4. *To Maintain Health*—The Local Government Act introduces a further element into the matter of the maintenance of health. Under the Act local authorities receive block grants for many purposes, including health, and it is expressly stated that these grants are given on the definite understanding that a reasonable standard of efficiency and progress in the discharge of public health functions will be maintained by the local authority. It is further stated that the Minister of Health has power to reduce these grants if the health of the community or any section of the community is endangered or likely to be endangered by any action or want of action by the local authority. It will therefore be seen that there is a definite financial stimulus given to local authorities to do all in their power for the health of the communities they control.

It may be suggested that these very large provisions and concentrations in respect of public health and medical work made by the Local Government Act of 1929 are likely to lead to a state medical service. I should not be at all surprised if this were the result so far as the hospital service of the country was concerned, for it will be seen that the vast majority of the hospital beds in England is in the hands of the elected representatives of the people.

On the other hand the Local Government Act of 1929 does not interfere with the National Health Insurance Acts under which panel practice is conducted, the essential element of which is the private medical practitioner. Some 15,000,000 insured persons are catered for by some 15,000 doctors who are under contract to render treatment of a kind which can, consistently with the best interests of the patient, be properly undertaken by a general practitioner of ordinary professional competence and skill. This form of practice is in a sense a private medical practice in so far as there is free choice between doctor and patient, but it is also in a sense a State medical practice as part of the payment for the medical practitioners comes out of State moneys. As it stands the service is mainly, if not only, a general practitioner service and its extension, although it has been considered, has not matured. Extension is needed in respect of consultant and specialist services, a hospital service, a nursing service, and laboratory facilities for diagnosis and treatment.

The service and its projected extensions are concerned only with the cure of disease. Some insurance medical practitioners, however, are turning their attention to the prevention of disease. They are endeavoring to reduce sickness by the education of their panel patients in health. The patients are encouraged to seek the advice of their panel doctor as to how to keep well, to come to him without delay as soon as they feel unwell, and to undergo regular periodic overhauling at other times. In this way the doctor and patient coöperate toward the detection of disease in its early stages and the prevention of disease and the maintenance of health. The doctor recognizes that it is to his advantage to have no ill patients on his panel.

It may be that generations may elapse before a whole-time State medical service is established, if at all, but it is well to observe that the private doctor is being pressed increasingly into the service of the State. The bulk of general medical practitioners hold no office of profit directly under the Ministry of Health or local health authority but various Acts of Parliament place certain statutory obligations upon them. A general medical practitioner is liable under Statute in the following respects:

1. He must notify births within 36 hours.
2. He must certify stillbirths.
3. He must certify deaths.
4. He must notify cases of infectious disease.
5. He must notify cases of industrial poisoning.

In addition he may be called upon to perform any of the following duties:

6. To act as an insurance practitioner.
7. To provide medical assistance and treatment for the poorer inhabitants of the district in which he lives.
8. To act as a public vaccinator.
9. To act as certifying factory surgeon.
10. To certify insane persons.
11. To certify feeble-minded persons.
12. To act in an emergency when called in by a midwife, and from time to time to give certificates relative to the removal of infectious cases to hospital, disinfection, removal and burial of dead bodies, etc.

As a result of all these changes and State duties the general medical practitioner in England is becoming more and more alive to his responsibilities as a State medical practitioner. The importance of the prevention of disease is now taught him as a student on every possible occasion throughout his medical course. More recently the importance of public health as a subject in the medical curriculum has been considered. Public health was previously a subject relegated to a second place in most medical schools but is now receiving increasing attention.

THE TREND

I have indicated what are likely to be the immediate fruits of the Local Government Act of 1929. But to my mind what is most important about this Act is that it shows that the nation is conscious of the need for health and has declared for a policy of health. It is likely that this conscious declaration of policy by the government and local authorities will do more to stimulate public health progress than the passing of the Local Government Act itself.

One of the first results of the working of the Act will be that the government which already plays a part in promoting research will play an even greater part in the future, and that local authorities in England which do little if anything by way of research will be stimulated through the hospitals, and laboratories, and field work that they control, to take their share in this important development, for it is on the findings of research that all medical and public health progress is made. In Scotland a Scientific Advisory Committee on Medical Ad-

ministration and Investigation has been set up to advise the Scottish Board of Health. When the huge number of deaths per annum from heart disease, respiratory diseases, cancer, tuberculosis and diseases of the nervous system are remembered, it will be seen that there is much work for such a committee to do.

I have outlined to you what the present trend of public health in England is, but I am quite sure that the public whose consciousness of the need for health has been thoroughly aroused and whose elected representatives are acting with definite intent to secure health for the people will ask of the medical profession—"What must we do to be healthy?" It is, after all, that question which we who are the health advisers of local authorities must prepare ourselves to answer.

It is at this point that we turn to the physiologist and tell him that he must advise us as to what normal life processes are and as to the conditions under which they may be maintained. We appreciate that the earlier in life correct habits of living are inculcated the better and stronger and more resistant will be the adult product. It was for this reason that maternity and child welfare work was begun. It is true that we have antenatal clinics, but these clinics are designed more with the idea of protecting the mother in childbirth than of trying to secure that the child when born has been properly nurtured in the mother's womb. This conception of an antenatal clinic must be realized, for the processes of nutrition are profoundly affected during the antenatal period and in early life and good feeding and habits in later life will not wholly compensate for errors in the early stages.

We must come back to a study of the various processes of nutrition and learn the way of health. We must make an endeavor to recognize the essential processes which will make for healthy living, and ask the physiologist to become definitely a public health worker.

Recently a committee in England has been set up to advise the Minister of Health on how the recent advances in the science of nutrition can be best utilized in the interests of public health, and that committee is at work. It does not hope to accomplish the ideal of planning good health and continued good health for everyone, but I am quite sure that it will do something toward that end.

The Relation of Public Assistance to Public Health in England*

SIR ALLAN POWELL, C. B. E., HON. F. A. P. H. A.

Chief Officer of Public Assistance of the London County Council, London, England.

FOR over 30 years I have been concerned with that section of public health administration in the County of London which is related to the provision and maintenance by the Metropolitan Asylums Board of public hospitals for infectious, children's, and mental diseases. Two years ago, however, when the work of the board was transferred to the London County Council, I entered on another phase of public work and undertook the organization and management of the new department formed by the County Council to take over the public assistance duties of the 25 separate boards of guardians of the poor till then functioning in London.

Public assistance in its widest meaning may be held to include all those services for the individual the cost of which is wholly or partly borne by public funds, i.e., national taxes and local rates. It includes the provision of houses, maternity and child welfare, education, unemployment pay, and the maintenance of health; it touches the life of the individual at almost all points from the cradle to the grave, and vast sums are spent on these services. I am using the term, however, in the more limited sense in which it is generally understood—the relief of destitution.

This considerable change in the orientation of my activities has enabled me to survey the familiar questions of public health from a new point of view. It is very stimulating to examine a well known landscape from a different standpoint and in a new light, and I trust that my first impressions of public assistance and my new reflections on problems which, as I gather, are likely to command increasing attention in the United States. I say this because the question of public assistance in your country appears to be coming into the field of current political thought and will, therefore, thrust itself to an increasing extent into your affairs as administrators of public health.

* Read before a Special Session of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

Going from public health to public assistance as I have done, arouses at once a very strong feeling of travelling from a country which is comparatively new to one very much older, and necessarily much richer in history and traditions—some such feeling, in a sense, as is aroused in an American on his first visit to Europe. Let me give you an instance straight away. I undertook my new office at the beginning of 1930 and I found that the Act of Parliament with which I was mainly concerned was The Poor Law Act, 1930. The key section of that Act and the duty of the local authorities is as follows:

Section 15 (1) (a) (b)

To set to work all such persons, whether married or unmarried, as have no means to maintain themselves, and use no ordinary and daily trade of life to get their living by.

To provide for the necessary relief of the lame, impotent, old, blind and such other among them being poor and not able to work.

There is a rhythm and a style in the language which makes it completely different from the phraseology of modern statutes. You may possibly be reminded of the pleasant sensations that you enjoy when you raise to your lips a glass of '60 port, or of Napoleon brandy, if such a simile may be permitted in this assembly. If you are connoisseurs of literature you will no doubt say that that clause can only have been written at some time earlier than Milton and later than Sir Thomas Moore. The clause is, in fact, a quotation from the great 43d Act of Elizabeth and is dated 1601. The law of public assistance in England today is, therefore, in its basic elements the law instituted by the wisdom of Queen Elizabeth's famous group of councillors, among whom were men like William and Thomas Cecil, Francis Bacon and Edward Coke, whose fame is still familiar to the modern world.

While, however, public care for the health of the individual had its origin in Tudor times with public provision for the relief of destitution, its development is essentially a matter of the 19th century and after. It is true that a Mayor of Nottingham was presented at a Court for sundry misdemeanors in 1512 for starting a muck hill, and that Shakespeare's father was fined in 1552 for throwing rubbish into the street, but that was under local manorial bye-laws and neither the Queen's Ministers nor Parliament, though deeply concerned with the poor law, were called upon to consider any public measures dealing with sanitation.

Until the 16th century, the relief of indigence, including the care of the sick poor, was adequately provided by the various corporations that existed within the church, such as hospital foundations, almshouses and the services provided by monastic establishments. It was

ordained by Kings before the Conquest that the poor should be sustained by parsons, rectors and the parishioners "so that no one shall die for lack of sustenance." The primary effect of the reformation, however, was to make the Church in England into the national English church and it followed that the organization of help for the poor became a matter for the national government. This is why the legislature at the end of Queen Elizabeth's reign passed the Act already referred to which commanded the local parochial units to raise funds and appoint officers for providing relief for poor persons who were not able to work and for the sick. There seems little doubt that the function of the central government was to secure the passing of laws and that it had no regular machinery for controlling local administration. The actual provision, therefore, for the sick and poor continued to be a parochial affair, and there were naturally great diversities of treatment, ranging from many admirable experiments down to many grave abuses.

Relief given was necessarily either institutional or domiciliary. In the case of sick people, institutional care was usually provided in the mixed workhouses. If the sick could be looked after in their own homes, they were attended and "physicked" by the parish doctor.

Perhaps the most significant of the changes made by the great Poor Law Amendment Act of 1834 was the establishment for the first time in English local government of the principle of central executive control over local administration, or, in other words the institution of a central body and the appointment of inspectors, thereby converting the administration of the poor law into a function of the national government. The local units of administration were inevitably and properly retained for a service which is intensely local in its incidence, but it was found that the drastic reforms necessary and the maintenance of an adequately high standard of administration required the direction of a central authority.

After 1834 there arose a noticeable appreciation of the extent to which poverty in many cases was dependent on health. The Poor Law Commissioners reported that

... prominent and pressing were the means of averting the charges on the poor rates which are caused by nuisances by which contagion is generated and persons are reduced to destitution. All epidemics and all infectious diseases are attended with charges immediate and ultimate on the poor rates . . . the amount of the burden this produces is frequently so great as to render it good economy on the part of the administrators of the poor laws to incur the charges for preventing the evils where they are ascribable to physical causes.

As a result of this changed outlook, to which impetus was given by the humanitarian reaction following the evils consequent upon the indus-

trial developments and the uncontrolled movement from country to town during the first quarter of the century, the Royal Commission which led to the passing of the Poor Law Reform Act of 1834 was followed by another Commission on the Health of Towns and Populous Places. This body reported in 1845 and there followed the passing of the first Public Health Act of 1848—the “ground work of sanitary legislation.” The movement owed its initiation to the same group of thinkers and administrators, of whom Bentham and Chadwick were the best known names, which had inspired the reform of the poor law. Not unnaturally the leading feature of this change was the institution for public health also of a central authority, which from the beginning took and kept a leading part in the development of public sanitation. The local sanitary work was entrusted to the town councils and thus began another local and independent health service working on very different principles from those inspiring the ancient poor law services.

Unlike the poor law board, the central public health authority came into existence not to reform what was already there but to create a new thing. This different attitude has persisted until today, and I think that on reflection we shall find that this is necessarily so. The demand for public assistance grows up from below, but public sanitation has to be imposed from above. To put it in a very homely way, if a man is hungry he asks for food, but if he is dirty he has to be told that he ought to wash. The dirty man who asks for a bath is the product of an educational process which has been initiated from above. To take an even more homely example, it is a common experience that the small male animal of the human species readily displays his willingness to eat as much as he can get, but one of your own cartoonists has impressed on us the truth that small boys display a remarkable ingenuity in delaying or avoiding ablution.

To revert to a more official statement of the position—the central authority has found it constantly necessary to restrain local units of government from giving public assistance too freely, whereas a central authority has constantly had to stimulate local units of government to show more activity in providing sanitary services, and for some decades now it has been the custom of Parliament to make percentage grants from public funds toward the expenditure of local authorities in order deliberately to encourage such local authorities to spend more and more on public health.

You will have observed that hitherto I have spoken of public health as the equivalent of public sanitation and that, apart from the cure of the destitute sick, was its content, but, by 1875, England was thoroughly educated in the appreciation of sanitation. Disraeli was

able to make the epigram when he introduced his great Public Health Act of 1875 "*Sanitas sanitatum, omnia sanitas.*" Englishmen were wont with no little complacency to boast about their Doultonware, the evangelizing qualities of Pear's soap, and the triumphs of the plumber's science in our cities and towns. Public health at this time was indeed largely a matter of pipes. Pipes to bring clean water, drain pipes and sewage pipes performing their unseen cleansing tasks, and large tubular pipes in the form of chimneys to cast in the face of an affronted heaven the black clouds of smoke that were the celestial sign of our abounding industrial prosperity.

Since the beginning of the twentieth century, however, public health administration has extended its scope very widely beyond the limits of sanitation as ordinarily understood. Instead of being mainly concerned with all those measures, multifarious as they are, which are necessary to prevent infectious diseases and other menaces to the health of the community, public health administrators are reverting to the first conception and are becoming more and more concerned with the personal health of individual members of the population. An example of this shifting of the point of stress is shown by the fever hospitals of London which were provided in order to isolate persons suffering from infectious disease, with a view to checking the spread of such disease throughout the city. A continuous and candid examination of the facts, however, revealed that such isolation did not really affect the spread, or otherwise, of the disease and that the provision made was really fulfilling the service of giving to each individual sufferer the care and cure which he would have found it difficult to obtain in his own home without such public aid. The Metropolitan Asylums Board, therefore, led the way in providing what the Webbs in their *English Local Government* describe as the magnificent hospital system which afforded treatment for individuals who were suffering from diseases requiring the specialized knowledge and equipment which could only be provided by a large authority working on progressive lines.

What was described by the Minister of Health responsible for the measure as the greatest change in English local government for the years was brought about by the Local Government Act, 1929, which came into force on April 1, 1930. References to various aspects of this great measure from different angles will no doubt be made by my British medical colleagues at this meeting. It is enough for me to point out that it swept away the boards of guardians of the poor and handed over practically all their duties to the county and county borough councils. The most difficult and thankless of these duties was undoubtedly the granting of domiciliary or outdoor relief on other

than health grounds, especially to the able-bodied, a problem which appears merely to increase in difficulty with the passage of time. That part of the change with which public health administrators are concerned is the one which for the first time brought the two public medical services under one control in each area. In London (and generally throughout the country) the Public Assistance Committee of the Council is charged with the relief of destitution and the Public Health Committee with the management of the hospitals and with the control of all medical and nursing working. The principal points of contact are (1) in the provision of domiciliary medical relief, and (2) in the arrangements for the admission of destitute patients into hospital.

The county is divided into districts, each with its district medical officer who is for the most part a general practitioner in the neighborhood and whose duties involve attending the destitute patient in his home or at the medical relief station or dispensary of the district. The district sub-committees administering relief, of which there are 74 in London, receive the reports and recommendations of the district medical officer in all cases of persons receiving out-relief requiring medical attention and special care or nourishment in their homes. In the case of able-bodied men who as a condition of receiving out-relief are required to attend work or training centers, an examination by the district medical officer is a necessary preliminary to such attendance. In London the number of visits to the homes of patients paid by the district medical officers in the year ended September, 1930, was 60,000 and the number of patients' attendances at medical relief stations was about 230,000. In the whole country there are some 4,000 district medical officers.

With regard to the hospitals provided out of public funds, these, up to the 1930 change, had been almost entirely established by the guardians of the poor, and in modern times the sick wards of the general workhouses had developed in many parts of the county into first class hospitals. Even with the hospitals of the Metropolitan Asylums Board in London, it is true to say of every disease admissible that the admissions started with and were limited to the destitute class and that in the natural order of things it was found necessary to make the need for treatment rather than lack of means the basis of admission, and the legal limitation on admission was removed.

It was scarcely likely that public opinion would rest content in the case of the guardians' hospitals that a relieving officer's certificate should be the open sesame and that destitution should be the sole qualification for admission. So in these hospitals too, the necessary qualification of destitution had for a long period been so widely in-

terpreted that it included many who would have been excluded by a strict application. With the Act of 1930 came the transfer of all these hospitals to the county and county borough councils, and this naturally means the transformation of the guardians' hospitals into municipal general hospitals and the opening of their doors to the general public. The London County Council is now responsible for some 100,000 beds of all kinds and the individual citizen, therefore, has a wide range of public resources from which to draw—not only for infectious and mental diseases but also in respect of what the ancient Greek would have called his "self-regarding" necessities.

It is not unnatural that, when charitable people provide something that is really very good with the intention that it shall be used for the very poor, the ultimate fate of such good things is to be used by better-to-do people who have the intelligence and energy to appropriate them, and it is often said that this has been the fate of some of our most ancient educational foundations. This process should be less facile with public control, but it will need the vigilance of the local authority to insure the observance of the right of prior admission which the Act of 1929 gives to the destitute poor for whom the hospitals were first provided and by whom they have so far been filled. At the same time it will have to meet the new demands from classes ranging above the poverty line, certainly up to the lower middle classes, which need ampler hospital facilities. In a word, we have to reconcile the view of the President of the English Society of Medical Officers of Health of last year who wants "to get and cater for the respectable, independent, middle, or lower middle and working classes who cannot afford the private nursing home and do not like charity" and that of the late Lord Knutsford, one of the outstanding figures in the English hospital world to whose personality is very largely due the re-creation of the London Hospital with its 800 beds, flourishing medical colleges, laboratories, nursing training school and so forth. Lord Knutsford died in the hospital and the comment was widely heard that this was a fitting end. But when the surgeons insisted on his removal to hospital he made the characteristic reply "The hospital is for the sick poor and not for the likes of me."

Very closely linked up with this question is that of payment according to means for hospital treatment. The old poor law regarded the family as a unit and provided that

... it shall be the duty of the father, grandfather, mother, grandmother, husband or child of a poor, old, blind, lame or impotent person or other poor person not able to work if possessed of sufficient means, to relieve and maintain that person and the authorities were entitled to obtain orders of maintenance

against the liable relatives. This right to recover from liable relatives the whole of the expenses of maintenance, or such part as in the opinion of the authorities they are able to pay, is renewed in the Act of 1929. The London County Council have taken the view that the duty of assessing and collecting contributions from those who receive

. . . services rendered or relief granted out of rates or taxes to an individual or family upon an examination of the economic or other circumstances of their case, including relief in all forms, maintenance and treatment in hospitals and institutions (except for infectious disease)

shall be concentrated in a single department and that the Public Assistance Department. This may seem to run counter to the views of those who claim that the change was intended to depauperize sickness and remove the stigma of pauperism by which is meant the interposition of the relieving officer and inquisition as to means. But a change of words does not involve a change of things, and any limitation as to means put on admission to the hospitals must involve the ascertainment of the facts. Similarly, whatever officer has the duty of ascertaining the facts and collecting payment, will have to make inquiries similar to those now made by the Public Assistance Department and will be no more popular than any other official who has been charged with those duties in the past. I doubt whether the stigma of pauperism lies in the fact that inquiries as to means are made, nor in the particular title of the officer making the inquiries. A more fundamental reason must be found, and I think it lies in the fact that until recently the only people who received that form of state assistance based on the ascertainment of needs, which was called poor law relief, were a limited number of the very poorest of the community, the class which included the dirty and ignorant, the ill-mannered and depraved. The "paupers" were a class apart from the rest of the community, losing all links with normal life and, if in institutions, they were known by their apparel. They were regarded as a class to be deterred and the spirit of deterrence even entered into the question of medical needs.

The idea of stigma, aged and deeply rooted, cannot therefore be wondered at, but the public attitude toward poverty has greatly changed. In the first place the numbers of necessitous persons are actually and relatively so much greater that they cannot be regarded as a separate class or as abnormal cases. Recourse is had to relief just as to other forms of social assistance, and the principle of deterrence is now less openly proclaimed, if not forgotten.

The transfer of the poor law services to an elaborate organization of government such as the county councils means the administration of what has for centuries remained essentially a separate service in con-

junction with other services of more recent origin destined to meet requirements which are the product of an ever increasing complexity of social organization. The reorganization of public assistance in co-operation with these other services should enable it to become more scientific in method and constructive in purpose than in the past, and in no branch of public assistance more than on the medical side.

I will close by touching very briefly one or two other considerations affecting public assistance and public health. In industry by rationalization and by the trend toward public utility companies, in the home life by the increasing volume of public services paid for by public funds, the tendency is to supplant individual by communal effort. The spirit of deterrence which marked the old poor law was perhaps the offspring of individualism in its extreme form. Benjamin Franklin when visiting London in 1766 said

. . . The day you passed that Act (43 Elizabeth) you took away from before their eyes the greatest of all inducements to industry, frugality and sobriety, by giving them a dependence on something else than a careful accumulation during youth and health for support in age and sickness. I think the best way of doing good to the poor is not by making them easy in poverty, but leading or driving them out of poverty. In my youth I travelled much and I observed in different countries that the more public provisions were made for the poor, the less they provided for themselves and of course became poorer . . . There is no country in the world where so many provisions are established for them, so many hospitals, so many almshouses . . . in short you offered a premium for the encouragement of idleness and you should not wonder now that it has had its effect in the increase of poverty.

If, as I think is true, the stigma of pauperism is dying out it is not because there is less but because there is more recourse to public assistance in one form or another and because the vast and rapid extension of public assistance in forms other than poor relief indicates a fundamental change in the relation between the state and the individual. That the developments in question were themselves inspired by a desire to prevent "pauperism" cannot disguise the fact that they make substantial calls on the public purse under various names while the sanguine hope expressed at each successive stage of social amelioration that poor relief would be *pro tanto* successively reduced, is not yet realized.

The problem of how the community is to provide for the needs for which the individual cannot provide, and which the public conscience demands should be met, without creating a universal spirit of dependence and stimulating the demand for public assistance by each new provision of it—without, in other words, yielding up the freedom of a strong and virile people—was never more insistent on the attention of the man in the street and of the statesmen in the cabinet than in the

present day. In the solution of the problem, public assistance and public health administrators can in coöperation play a large part. The public assistance side has, perhaps, the less popular rôle of emphasizing that the family unit is still the prime factor in our social structure; that running through all our social legislation in the past has been the theory that it is the duty of the family to help any member who falls into need or distress of any kind; and that this is true of sickness as of any other of the hardships of human life, against which the family is the natural protector.

If public assistance tries to preach economic wisdom, it will not, it is true, receive the applause of the market place but it may deserve the approbation of the judicious. I notice with great interest that the charitable social work which in many parts of the United States fulfils the function of the English poor law is carried out by societies which use the title of Family Societies, and that the gentlemen in the United States who may be said to correspond with the English relieving officers, are known as Family Rehabilitation officers. I must admit that we should want some acclimatizing even to the modest addition of "F" to the familiar initials of "R. O."; but behind the question of title there lies again the principle that public assistance administration should follow up all the numerous channels through which state and municipal help and specialized treatment are given to individual members of family groups and should still hold before each family the sense of its corporate existence and the idea of mutual help and independence.

Public Health Service in Britain Education and Training*

CHARLES PORTER, M. D., HON. F. A. P. H. A.

Medical Officer of Health, St. Marylebone, London, England

THE orientation of the public health organization in Britain is more definitely medical than is the case perhaps anywhere in the universe. Even before it was solidly established by the Public Health Act, 1875, and the medical character firmly and legally was conferred upon it, the intention that it should be so was clearly shown. Numbers of sanitary and health bodies throughout the country, conspicuously in London and Liverpool, recognizing this intention, early in the 19th century appointed medical officers, the example they set being followed soon by others. In the Acts of Parliament empowering such appointments references were made to non-medically qualified officers—surveyors or engineers and inspectors of nuisances or sanitary inspectors. In spite of this, however, and the outstanding importance of the work that experts in engineering and such like matters could perform at that date, the view apparently taken was that the assistance really required was such as could be provided by individuals trained and qualified in medicine. When the Act of 1875 came into operation no room for doubt upon this point was left.

THE MEDICAL OFFICER OF HEALTH

The authorities declared responsible for health conditions in the various parts of the country—named by the way “sanitary authorities” in this connection—had specifically imposed upon them the duty of appointment, first and foremost, of a person fit and proper to be a medical officer of health, and secondarily others, also fit and proper, to be inspectors of nuisances, surveyors, etc. Going further, the Act laid down certain provisions with regard to the qualifications of the medical officer of health, forbidding at once the appointment of any person to the post unless a legally qualified practitioner.

At this time there was no call for any particular qualification in the case of the other officers mentioned, i.e., the inspectors and the sur-

* Read before a Special Session of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

veyors. For that matter there was not then any actual reference to qualifications additional to those usually possessed by medical practitioners in the case of the medical officer himself. Various of the universities and medical schools, however, recognized the need for additional training and set about providing it, with, at the end, the inevitable examination and a degree or a diploma conferred upon such as complied with the rules of the teaching bodies and satisfied the examiners. The object of the teaching and examining bodies was, avowedly, to assist the government and the local sanitary authorities and in due course this was so very definitely recognized that there was introduced into an act of parliament having specific reference to local government (The Local Government Act, 1888) a provision that in no county or district with a population of 50,000 or more shall a person act as medical officer of health unless he has held certain offices, or in addition to a medical qualification holds and is legally qualified and registered as the holder of a diploma in sanitary science, public health or state medicine.

These expressions were used for the reason that the qualifications offered by the teaching and examining bodies were a doctorate in state medicine, in the case of London University particularly, a bachelorship in the science of public health (University of Edinburgh, Glasgow, etc.), and a diploma in public health by various examining bodies and universities.

The qualification being a registrable one the matter became a concern of the General Medical Council of Great Britain, and in due course this body laid down, and from time to time since has revised and amended, certain rules regarding the teaching and examining of persons for diplomas designed to secure that there shall be registered only such diplomas as are granted under conditions of education and examination satisfactory to the council.

EXAMINATION FOR QUALIFICATION

These examinations for degrees or diplomas in public health are not state affairs; nor are they conducted by or under the auspices of a civil service commission. The General Medical Council is, however, a statutory body and wonderfully powerful so far as regards the enforcing of any rules it may lay down upon institutions and bodies that set themselves up to provide education or carry out examinations. The approval of the council must be secured by those who teach and they must provide at least the minimum amount of instruction prescribed. The examining bodies must also comply, and the examinations they conduct are open to supervision and from time to time are supervised by representatives of the General Medical Council.

One of the advantages which this system appears to possess over the civil service commission examination is that the candidate is tested not merely for an appointment but to discover if the degree of his training and education is sufficient to justify certification of fitness for engagement in the work of the position. A prominence, therefore, it may be presumed is given to the training and education; and those concerned in examining, as well as those engaged in attending to the teaching, are encouraged to make improvements and to look for directions in which advances may be made. In Great Britain certainly, there have been such effects upon the two bodies named. Upon the General Medical Council, the body dictating to the others, there has been an effect of stimulation also, as shown by the frequency with which rules have been revised, always in the direction of increasing the stringency, requiring a higher and higher degree of efficiency in the teaching bodies, of the students attending the courses, and in the examinations.

EDUCATION AND TRAINING

As a fact, within the space of a comparatively few years such changes have taken place that practically necessitate the devotion by candidates for degrees or diplomas of whole time for a period of 12 months (2 years in the case of degrees) after they have secured a medical qualification and given, at least, 1 year to medical practice.

As showing the readiness of teaching and examining bodies to encourage advance, the case of the London School of Hygiene and Tropical Medicine and the University of London may be quoted. Opened only 2 years ago, the school provides today a course in public health and preventive medicine which, though designed to meet the requirements of the General Medical Council, covers ground infinitely wider than is called for by that body in which there is a coördination of subjects, and among the teachers to a degree not previously attempted in Great Britain certainly, and probably not anywhere else. In the course the attention devoted to field work, though considerable, is perhaps less than in other schools, much more time being given to a consideration and discussion of various aspects of preventive and public health work by specialists engaged in field or research work.

Among subjects dealt with in the session 1930-1931 under the scheme may be noted a series on Psychology by Professor Millais Culpin, recently appointed a member of the staff of the school as Professor of Medical Industrial Psychology; lectures on diseases common to man and animals; on the Laws of Inheritance by Professor Crew of Edinburgh University; on International Hygiene by Sir George Bu-

chanan; on Industrial Hygiene by Sir Thomas Legge, Professor Collis, and others.

The examination provided by the University of London is conducted in such a way as not only to comply with the rules of the General Medical Council but also to place it on a level as high as that reached by the teaching. The qualification awarded is in the form of a diploma, though it may be noted that the university also grants a degree in the shape of a doctorate in state medicine, open to graduates in medicine of the university and holders of the bachelorship of medicine.

EXAMINING BODIES

Apart from the university there is in London an examining body set up jointly by the Royal College of Physicians of London and the Royal College of Surgeons of England.

Outside London the examinations held are conducted by various of the universities. In Scotland, in addition to the universities, there is in existence a conjoint board of the colleges and faculties in Edinburgh and Glasgow similar to that examining in London. Not all of those who take the course of study sit the examination, the number of candidates annually in London alone being somewhere in the neighborhood of 150. Of these, at the first attempt, approximately two-thirds qualify for the degree or diploma.

In the provinces the number sitting is probably much less. Some of those who secure a qualification have no intention of entering the preventive medical service; others seek appointments abroad, and the remainder, the minority it may be, endeavor to enter the home service, competing for the occasional vacancies that occur in the various branches, and those, in the case, at any rate, of medical officer of health posts, must by law be thrown open to all who are qualified, through a public advertisement issued by the appointing authority who selects the person preferred after a series of interviews.

Before the officer can begin to operate, his appointment must be approved by the Minister of Health, the reason for this interference being that some part of the salary of the officer is paid out of central government funds. This is regarded, in the case of the medical officer of health at least, as giving the government a degree of control and making the officer liable to an extent to act in a national as well as a local capacity.

The other medical officers serving in departments and branches of public health and preventive medicine, even though their duties may be largely clinical, are commonly expected to hold the ordinary public

health qualifications. Quite usually they are offered by the candidates, many of whom anticipate securing higher administrative positions. Recently in certain branches additional qualifications or training have been demanded by the minister. To these reference is made later, the intention at the moment being to discuss questions affecting the education and qualification of certain non-medical sanitary health officers.

THE SANITARY INSPECTOR A HEALTH OFFICER

Of these the first to be referred to is the sanitary inspector, partly because the office was created at or about the same time as that of the medical officer of health, with whom he shares the distinction of being statutory. As in the case of the medical officer of health, his appointment is compulsory upon the local sanitary authority, who may only choose a person qualified in accordance with rules of the minister of health, who must also approve the officer chosen.

The sanitary inspector, it is recognized, is an officer peculiarly British, being found in most parts of the Empire. In some countries there exists, I am aware, a feeling more or less of contempt for the type of work that the inspector does or is supposed to do. To my mind, and speaking out of a very considerable experience, this contempt both for the work and the officers can be carried too far. Without hesitation I say that the public health owes a very great debt of gratitude to sanitary inspectors, is still in their debt, and likely so to continue for a very long time. Also I believe those who in Britain linked the inspector with the medical health officer, made his appointment statutory and compulsory, and provided for the imposition of conditions in relation to qualifications, were blessed with vision. The one mistake made was in regard to the name applied to the office, although it is very difficult to suggest an alternative to "inspector," which is the part of the title that appears most objectionable and in general most inaccurate.

At first the requirements imposed in respect of qualifications were a little vague, but as a result of demands on the part of the inspectors themselves for instruction, and a willingness on that of the medical officers of health and other members of local authorities' staffs—engineering, legal, etc.—to provide instruction, the type of qualification required soon came to be recognized. Early in the field in this connection, with the providing of assistance to the authorities so far as the selection of suitable officers was concerned, by arranging for the holding of examinations and the granting of certificates, was the Royal Sanitary Institute. In due course this became the standard qualifica-

tion and throughout the country teaching institutions—the schools of technology, and in some places the universities—arranged courses of instruction for individuals desirous of sitting the examination and taking the certificate which might assist in securing appointment. Actually no qualification was specified by the central authority as essential to insure approval to an appointment made by a local authority, except in the case of London, until after the close of the Great War.

It was hopeless, however, for any individual to expect to be appointed who did not hold the certificate of the Royal Sanitary Institute, with, in addition, educational certificates of various kinds in respect of hygiene, physiology, and technical subjects, such as building construction. With the advances that occurred in connection with public health and preventive medicine, and for which he was to some extent responsible, the sanitary inspector kept steady pace. The grade of man adopting the vocation rose so high that it was found possible to give him greater responsibilities, and to entrust to him work of importance from the preventive point of view; in connection, for example, with epidemiology, food supervision, and so on.

Following such increases in responsibility and improvements in position came a recognition of the need for a qualification more specific and even higher than those already more or less accepted. In the demand for the qualification none were more insistent than the officers themselves individually and through their organizations. In meeting the demand no attempt was made to set up anything in the nature of a state examination. Instead the Minister of Health called upon the Royal Sanitary Institute and a body known as the Sanitary Inspectors' Examination Board which existed for the purpose of examining persons seeking appointments in London to unite and form a joint examination board. Having secured agreement on the part of these bodies, the Minister issued an order declaring no person qualified for appointment as sanitary inspector unless he was the holder of the board's certificate. The drawing up of the syllabus of the examination, the laying down of the conditions governing the examination, and the actual holding of the examination, the Minister left to the board, reserving only to himself the right to nominate a certain number of representatives. No payments out of government funds are made to the board in spite of the fact that the work done is obviously of the utmost national importance.

EDUCATION AND TRAINING

The teaching and training of persons desirous of sitting the examination is carried out in various institutions throughout the country

and in London. The course of instruction offered must be approved by the board, who insist upon a considerable amount of practical training in the field and of specific teaching by medical health officers.

The method of securing appointment as sanitary inspector is similar to that described in the case of medical officers, the supply here being probably even more in excess of the demand.

The Royal Sanitary Institute with the coming into existence of the Joint Board ceased to be an examining body for inspectors' certificates qualifying for appointment in England and Wales. So far as other parts of the Empire are concerned, however, its activities continue to be as extensive as ever. In certain parts indeed they are greater, e.g., in South Africa and in India, where, acting along with the government of the country in question, they set up joint boards and issue the only certificate receiving recognition. In certain provinces of Canada, in Australia, in New Zealand, in Singapore and the East, in West and East Africa, and the West Indies, there are examining boards, all of them in close coöperation with the Council of the Institute in London, who issue no certificate until the work and results of the examination have undergone scrutiny at headquarters.

WOMEN HEALTH WORKERS—THE HEALTH VISITOR

The faith and belief in the Royal Sanitary Institute throughout the Empire is immense; and it does not, at home, share the fate of the prophets in being without honor. The respect in which it is held is very great, and the extent to which the Ministry of Health and the local health authorities are prepared to trust and rely upon it practically unbounded. The part played in relation to the examination of sanitary inspectors has been explained. In the case of the other non-medical worker in the health department of the local authorities—the health visitor—the part is even greater.

Woman, in Britain at any rate, did not join the team of the public health department till about the end of last century. At that time, in order that she might have an official position and possess various powers of entry to premises and of taking action, she joined as a sanitary inspector, having sat the various examinations and secured the necessary qualifications. Once in office the woman showed her real value and importance and in a very short time all subterfuges were dropped and she was given a definite place in the organization. The title "health visitor" was coined for her, and the Royal Sanitary Institute undertook to hold examinations for the health visitor's certificate and issued a syllabus upon which various institutions in London and the provinces based courses of training.

As far as possible the institute sought to limit entries to women who had qualified as nurses or midwives, or both; but because the calling of health visitor was so attractive to women desirous of doing work of a social kind, provision had to be made for the training and examination of these and certain institutions of standing arranged to meet the need.

Arrangements of this kind continued to operate until the end of 1918, when the need was recognized for a single portal of entry to the profession of health visitor and for one examination qualifying for the certificate without which no woman was eligible for appointment under a scheme of maternity and child welfare to which the Ministry of Health made financial contribution.

As in the case of the sanitary inspector, the Minister turned once more to the Royal Sanitary Institute, and in due course a special board was established to conduct the examinations and to issue a syllabus of subjects for the guidance of training institutions and candidates. The Minister of Health himself issued various rules and regulations and laid down certain conditions that must be complied with before candidates could sit at the examination. Broadly there are 2 classes, (1) nurses who have completed a 3-years course of training either at a recognized general hospital or a recognized children's hospital, who have obtained the certificate of the Central Midwives Board, and who have attended an approved whole-time course in public health work lasting for at least 6 months; and (2) women, not being trained nurses, who have undergone an approved course of training in public health work extending over 2 years, together with 6 months' training in hospital, and who have obtained the certificate of the Central Midwives Board, without which, of course, no one other than a medical practitioner may practise as a midwife. All entrants to the service today whether trained nurses or not must take a whole-time course of instruction.

TEACHING AND TRAINING

The institutions providing facilities for training number round about a dozen, about half being in London and the remainder in various provincial centers. In all cases practical training is compulsory, and arrangements are made for this to accompany the more theoretical lectures and instruction at selected maternity and child welfare centers.

In some districts, the county of Durham particularly, arrangements are made for providing the teaching and training, while the student is working and receiving a certain amount of pay as probationary health visitor in the health department. The service given in these cases is regarded as payment made for the teaching provided. In other cases

the students themselves pay the necessary fees which are comparatively small by reason of the fact that the Ministry of Health makes a grant to the teaching institutions toward the cost of the training of each of the students. The fee for the examination is paid by the candidate. The examination is of a very searching character and consists of 3 written papers, each candidate being examined orally also by a board consisting of at least 3 examiners, 2 of whom are medical officers of health, and 1 a health visitor.

From time to time the examination is supervised by an officer of the Ministry of Health. When the rules and regulations of the Minister with regard to the examination were first introduced, it was felt that on account of their stringency they might lead to a serious reduction in the number of women seeking to qualify as health visitors.

Events have shown this fear to be without foundation, the numbers attending the recognized courses and facing the examiners being much more than adequate to meet the needs of the local health authorities. At the moment at least this is the case, and if in future there should be any falling off it will be the result rather of the unsatisfactory conditions as regards pay than of stringency in regard to training and examination.

THE POST OF HEALTH VISITOR

Having regard to the fact that the official title of this officer is very peculiarly British, perhaps it should be explained that mainly the health visitor is engaged in performing duties that do not involve actual nursing. She is defined indeed in the Local Government Order, 1930 (*Qualifications of Medical Officers and Health Visitors*), as a woman whose duties include the visiting of women and children in their homes for the purpose of giving advice as to the nurture, care and management of young children, and as to the health of expectant and nursing mothers. By health authorities, some nurses are, of course, employed, who work among school children, for example, and others who carry out more or less of what is called district nursing among persons not removed to hospital. Staffs of nurses for attending to patients suffering from infectious disease are attached to isolation hospitals. In most districts infectious cases are only exceptionally nursed at home.

The practice of calling upon one woman to double the parts of nurse and health visitor is followed in a small number of places, and in these there has been some sort of inclination to adopt the official title of public health nurse. Neither the practice nor the title, however, has been generally accepted, nor indeed are they regarded with favor. Despite the efforts of an odd body or medical officer of health

here and there, it appears certain that the older and less cumbersome and more accurate name "health visitor" will be retained. It is a fact, of course, that in the homes and by the people the woman is most commonly addressed as "nurse," but, by the same token, the sanitary inspector is rarely if ever called by that name, so that it would appear to matter little to anybody but the stickler exactly what they are called. I am a stickler and I like "health visitor."

So apparently does the Minister of Health, for in an order issued at the beginning of last year under powers granted to him in the Local Government Act, 1929, he uses it again in indicating to local health authorities that any person appointed to such a post must be a woman who, prior to April 1, 1930, has held the appointment of health visitor with the approval of the Minister, or who has obtained the health visitor's certificate issued by the Royal Sanitary Institute.

THE TUBERCULOSIS VISITOR

In the same order reference is made to another woman visitor as well as to certain medical officers who must or may be appointed by local health authorities. The particular visitor mentioned is the "tuberculosis visitor" whose duties in the main lie in relation to the tuberculosis dispensary and the homes of persons attending the institution or who are notified as suffering from tuberculosis. The purpose of her visits according to the definition is the giving of advice as to the care and hygiene of persons suffering from tuberculosis, and as to the measures necessary to prevent spread of infection.

The kind of woman suitable for the position is one who has obtained the health visitor's certificate or who is a fully trained nurse and has had at least 3 months' special experience at a sanatorium or hospital for the treatment of tuberculosis, or at a tuberculosis dispensary. In the Ministry order it is stated in fact that only exceptionally will an appointment by an authority of any person not so qualified be approved. The importance of the approval of the Minister to an appointment lies in this—without it no financial assistance will be given to the authority by the Minister toward the payment of the salary of the officer. In addition, of course, by laying down requirements as to qualification in orders and regulations the Minister insures that trained officers only shall be employed, creates a demand for training, and encourages teaching institutions to provide the courses of training.

VARIOUS MEDICAL OFFICERS

In addition to health visitors and tuberculosis visitors, as already noted, the regulations of the Minister issued in 1930 contain reference

to various medical officers who of recent years have joined the public health department organization of the local authorities to attend to particular sections of the population and to deal with particular diseases. In each case special qualifications and expert knowledge and skill are required, and it is in order to insure that local authorities shall appoint none but individuals specially qualified that the Minister has laid down his rules. The officers referred to in the order include a tuberculosis officer or medical superintendent, a venereal diseases pathologist, a venereal diseases officer, a senior maternity and child welfare officer, and a medical officer of an antenatal clinic.

Tuberculosis Officer—The requirements in regard to the tuberculosis officer or medical superintendent—meaning by the latter a medical officer in clinical charge of a residential institution for the treatment of patients suffering from tuberculosis in the early or curative stages of the disease, which contains not less than 75 beds, are (1) that they shall have had at least 3 years' experience in the practice of their profession, (2) have spent in general clinical work a period of not less than 18 months, of which not less than 6 must have been spent in a hospital as resident officer in charge of beds occupied by general medical or surgical cases, and (3) have received special training for a period of not less than 6 months in the diagnosis and treatment of tuberculosis.

Venereal Diseases Officer—The person appointed venereal diseases pathologist must also have had 3 years in practice, but in addition must possess a certificate given by a pathologist in charge of a laboratory approved by the Minister of Health, testifying that, under his supervision, the person, within the preceding 2 years, (a) has personally carried out not less than 500 serum tests for syphilis by a method approved by the Minister and is competent to perform such tests, and (b) has personally examined microscopically not less than 300 specimens from lesions suspected to be syphilitic, gonorrheal, or chancroidal, and is competent to conduct such examinations.

The qualifications for a venereal diseases officer, in addition to the 3 years' professional practice, are that he must be in possession of a certificate given by a venereal diseases officer of a treatment center at which not less than 500 patients attended for the first time during the 12 months preceding the issue of the certificate, testifying that he has attended at the treatment center for a period of not less than 3 months, and has received during that period not less than 130 hours' instruction in the modern methods of diagnosis and treatment of venereal disease.

Maternity and Child Welfare Officers—A person appointed senior maternity and child welfare officer must be in a position to show

either that he has held such a post with the approval of the Minister prior to April 1, 1930, or that in addition to 3 years' professional practice he has had special experience in midwifery and child welfare work and has been employed by a local authority under the Maternity and Child Welfare Act.

The conditions in the case of the medical officer of an antenatal clinic are that the person shall either have held an appointment approved by the Minister prior to April 1, 1930, or subsequent to qualification have had 3 years' professional practice and special experience of midwifery and antenatal work.

In the main, in these cases it is practical experience that is required; and in most instances that experience can only be obtained in the service of a local authority or in a special institution. The difficulty of securing it in certain cases is considerable, but actually there is no shortage in the supply of officers required.

Veterinary and Food Officers—The lists and descriptions given do not quite exhaust the number of officers included in the team of health workers engaged in or actually attached to the public health department of the local authority possessed of a reasonably complete organization. In Britain, even in quite large districts, the "bureau" system as it is seen in other countries and which, *prima facie* at any rate, suggests the existence of water-tight compartments, is not recognized. The medical officer of health being an executive and working officer is given general supervision of and responsibility for the whole department, the persons in charge of the various branches of work being responsible to him.

Among such individuals, in addition to those mentioned, there will be an officer in charge of food and veterinary work, who will necessarily and naturally be a qualified veterinarian. No special qualifications, apart from those of a veterinary surgeon, are laid down for this officer though very many have undergone special training at universities and veterinary colleges, and have secured special diplomas in veterinary hygiene. Control of the food supply, meat in particular, is part of the duties of such officers, though it must be noted that the sanitary inspector, having by law powers of inspection, seizure, etc., of food, has a certain position in this connection though occasionally he works under the veterinary officer as an inspector of food. Special courses of training in meat and food inspection are provided by a number of bodies throughout the country, and in London notably by the Royal Sanitary Institute. This body, after examination, grants a certificate of competence to act as inspector of meat and foods, which is very highly valued and approved by the Ministry of Health. Only persons who have un-

dergone the specific training and who comply with certain conditions, among them that they possess the certificate of qualification to act as a sanitary inspector, are admitted to the examinations. These, like those for sanitary inspectors and health visitors, are held at various centers throughout the country in addition to such as are held in London at regular intervals.

THE SCHOOL MEDICAL SERVICE

The School Medical Officer—The medical officer of health to a local authority is commonly the medical officer to the education authority of the district also, and is responsible for the medical inspection, supervision, etc., of the school children in the area. The staff required for these purposes depends upon the size of the school population but in addition to medical members includes also nurses. No special qualifications are prescribed for these officers, but so far as the medical members are concerned those who are appointed assistants generally possess a degree or diploma in public health, and use the appointment—as do very many of the other specialist officers, e.g., the tuberculosis and maternity and child welfare officers—as a stepping stone to that of medical officer of health.

The School Nurse—School nurses apart from their ordinary nursing qualifications are not called upon to produce any other. Several, however, are qualified to act as health visitors and a number of others also possess a special certificate in school hygiene which was established by the Royal Sanitary Institute some years ago, and for which special courses of training are obtainable in a number of institutions throughout the country.

THE RÔLE OF FIELD TRAINING

From what has been said it may be gathered that so far as Great Britain itself is concerned there is a very fair recognition of the needs in regard to the qualification of the various individual members of the health personnel. In addition it may be claimed that in general in the universities and elsewhere—schools of technology, for example—there is available an adequate amount of teaching and training for all grades. In all the courses of training it is noticeable that field work and practical experience occupy a considerable space. The chief reason for this is that there is insistence upon it in the syllabus of the examining bodies.

In the case of the person sitting for the degree or diploma in public health and the candidate for the certificate of the sanitary inspector, both must see actual work for a fairly long period in a public health de-

partment. The health visitor pupil also must work in a maternity and child welfare center during the whole of the time she is studying for her examination, i.e., a minimum period of 6 months. While there may be some who doubt the necessity and advantage of working in one department as an alternative to seeing methods adopted in a number of areas and institutions, it is noticeable that the Minister of Health in stating his requirements in the case of such officers as those to be engaged in venereal diseases and maternity and child welfare work, makes it a condition that they shall have had actual experience in a center.

Long as it is, this report does not pretend to be much more than a sketch of conditions as they exist in Great Britain in regard to the qualifications and training of health personnel. Those who desire further information may find the following orders, regulations, etc., useful: Details with regard to the training and examinations for degrees and diplomas in public health may be obtained from the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W. C. 1, England; and for the certificates of sanitary inspectors, meat and food inspectors, and health visitors, from the Secretary of the Royal Sanitary Institute, 90, Buckingham Palace Road, S. W. 1, London, England.

General Medical Council Resolutions and Rules for Diplomas and Degrees in Public Health, to come into force on October 1, 1931, is published by and may be obtained from Messrs. Spottiswoode, Ballantyne & Co., Ltd., London, England.

Maternity and Infant Welfare Service in England and Wales*

JAMES FENTON, M. D., D. P. H., HON. F. A. P. H. A.
Medical Officer of Health of the Royal Borough of Kensington, London, England

THE development of maternity and child welfare work has depended on two main factors—the desire to ameliorate individual suffering, and efforts to increase national efficiency. Both factors were stimulated by the Great War, which led to the discovery of large numbers of men whose low physical standard was found to be due in great measure to insufficient skilled attention in infancy and childhood; also the loss of large numbers of men created a national desire for an improvement in the rearing of children.

Four stages of development may be distinguished in England and Wales. From 1900 to 1914 there was a period of private effort and permissive legislation. From 1914 to 1918 was the period of encouragement of local effort by the government. From 1918 to 1930 there was a great development of State aid and control. Twelve months ago we entered upon a fourth stage following the introduction of the Local Government Act of 1929.

FIRST STAGE—1900 TO 1914

Before the earlier of these years, philanthropic agencies had been at work, and they received an impetus about 1900 from the awakening of public interest in the falling birth rate and the physical condition of the population as revealed by the experiences of the South African War. In 1904 a center where poor expectant mothers could receive free meals was established by voluntary enterprise in my own district of Kensington.

A series of conferences on infant mortality, organized by a voluntary committee in 1906, was opened; then several voluntary associations for promoting the health of mothers and infants were founded. The first infant consultation center was commenced in 1907 in the Borough of St. Marylebone; and the first school for mothers, from which infant welfare centers have sprung, was founded in 1907 in another London Borough, St. Pancras.

* Read before a Special Session of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

The medical inspection of school children was made obligatory in 1907; and in the same year an Act was passed empowering local authorities to require all births to be notified to the Medical Officers of Health within 36 hours.

Beginning in 1908, the government made annual grants to local education authorities in respect of schools for mothers. Thus it will be seen that in the earliest days the government regarded this work primarily from an educational standpoint.

SECOND STAGE—1914 TO 1918

The government issued a circular in 1914 laying down conditions under which they would pay grants in aid of maternity and child welfare work carried out by local health authorities and voluntary associations. The first of these was paid in the same year, and from that time onward the government has accepted responsibility for 50 per cent of the cost of all approved schemes, the remainder being provided by local authorities and voluntary associations.

The Notification of Births Act of 1907, which was permissive, was made compulsory throughout the country in 1915.

THIRD STAGE—1918 TO 1930

In 1918 the Maternity and Child Welfare Act was passed. It gave wide and comprehensive powers to local authorities, acting with the approval of the government, to establish services designed to safeguard maternity and to preserve the health of children under 5 years of age, after which they enter school and come within the jurisdiction of the school medical service.

The grant paid by the Government rose from £56,809 in 1915 to £770,000 in 1920 and £1,193,707 in 1930. Of this last sum, the amount paid to local authorities was £929,824, and to voluntary bodies, £263,883. The total expenditure of the Government and local authorities in 1930 was £3,050,638; in addition, considerable sums obtained from charitable sources were spent by voluntary associations.

In 1919 there were in England and Wales 1,550 infant welfare centers, of which 660 were conducted by voluntary agencies. In 1930 the number had grown to 2,893, of which 913 were conducted by voluntary bodies. The provision of antenatal clinics was not started until after the war, but by 1930 these had been established at 971 of the infant welfare centers; there were also 75 special antenatal clinics, while others had been established at hospitals.

In 1930 dental treatment was provided at, or in connection with, 1,061 of the infant welfare centers. The equivalent of approximately 2,083 women were devoting the whole of their time to health visiting. Over 16,000 registered midwives had given notice of their intention to practise in England and Wales. Of the 660,267 births in 1928, over 65 per cent were attended by these qualified women. Local authorities have provided, or are paying for, 2,561 maternity beds in 158 institutions for difficult confinements or for women who cannot with safety be confined in their own homes. They have also provided or are paying for 1,068 beds in children's homes, 518 beds in baby hospitals, 131 cots in observation wards, and 900 beds for children in convalescent homes. Under schemes approved by the government there are 97 day nurseries which undertake the care and supervision of children under 5 years of age; there are 94 homes for unmarried mothers and their babies and these have accommodation for 1,410 women, who are received before confinement and subsequently retained, with their children, for a period averaging 6 months.

Two hundred and forty-three local authorities have made arrangements for home nursing of cases of measles, whooping cough, gastro-enteritis, poliomyelitis, ophthalmia and maternal complications, and 217 have provided treatment for crippling defects in children. Artificial light treatment has been established at 158 centers. In 1929 the expenditure on additional nourishment for expectant and nursing mothers and their children was £247,052.

Since 1927, private maternity homes run for profit cannot remain open unless registered by the local authorities, who have power to inspect these institutions, of which there are over 3,000.

FOURTH STAGE—1930 ONWARD

This Act, which is one of the greatest measures of reform in recent years, abolished poor law authorities, with the result that municipal and poor law services for maternity and child welfare will eventually be amalgamated and placed under the control of one local authority. The government grants of 50 per cent of approved expenditure were abolished and replaced by fixed block grants. Moreover, an important change was made in the system of determining the amount of grant to be paid to each authority. While a grant of 50 per cent of approved expenditure had been found to stimulate wealthy authorities to action, it did not in all cases prove sufficient to encourage the poorer authorities to establish adequate services. To meet this difficulty, a differentiation has been made and the new block grants are calculated upon a formula giving greater help to the poorer authorities.

All maternity and child welfare grants are now paid direct to local authorities, who in turn are required to give appropriate sums to the approved voluntary bodies operating in their respective areas; and the supervision of the work of these voluntary agencies has been transferred from the government to the local authorities.

The Act secures that the supervision of children's health from birth to school-leaving age is entrusted to one and the same authority and makes it possible for that authority to supervise midwives working in their area. Finally, it requires that medical officers and health visitors must have specialized experience before they can engage in maternity and child welfare work.

ADMINISTRATION

The administration of maternity and child welfare schemes is carried out by a special statutory committee of the local health authority. The authority may co-opt for service on the committee persons specially qualified by training or experience in subjects relating to health and welfare; but not less than two-thirds of the committee must have been directly elected as councillors on the authority, and at least 2 members of the committee must be women.

There are still many infant welfare centers, day nurseries, baby hospitals, etc., which are conducted by voluntary associations; these bodies appoint their own committees of management and are free to carry out their own administration, provided that, if they receive government grant, they conform to the rules laid down by the local authority and submit to inspection by officers of the authority.

There is much diversity of opinion as to the management and staffing of the various institutions, but it is almost the invariable rule that the entire work in an area is under the supervision of the Medical Officer of Health, who is in administrative control of the whole-time or part-time maternity and child welfare officers carrying out the work.

The majority of the assistant medical officers are women. In those districts where general medical practitioners are appointed to give part-time service, opinion is divided as to whether it is preferable to select doctors who are in practice in the area in which the institution is situated or those whose private work is some distance away; but there is a growing tendency to appoint whole-time assistant medical officers in those areas where the amount of work is sufficient to give full-time occupation to one or more officers. In smaller areas it is usual for one assistant medical officer to undertake the work at the infant welfare institutions and also to act as school medical officer, and perhaps even as tuberculosis officer. Where practicable, it is now

the common practice of local authorities to appoint whole-time health visitors (who are generally hospital-trained nurses with special public health experience) to carry out home visiting and to act as superintendents of the various institutions.

While there has been a gradual growth in the number of voluntary associations, the increasing difficulty experienced in recent years by these agencies in securing funds from private sources has made it necessary for some to be absorbed into the municipal organization; and in other cases the local authorities have had to supplement very considerably the government grant. It seems inevitable that voluntary maternity and child welfare bodies will become more and more dependent upon local authorities for financial support. The decline in voluntary financial support follows the growth of public opinion that the work initiated by private enterprise and voluntary endeavor has been proved to be of such great value that it should be maintained entirely by the State taxes and the local rates.

Although it is inevitable that local authorities must gradually assume more control and accept greater responsibility in regard to voluntary associations, it is desirable that every effort should be made to retain the interest and valuable help of the large number of ladies who devote their time and money to the development of the work: they radiate an excellent influence which the service cannot afford to lose.

It is equally important to secure the sympathy of the medical profession and the midwives. This support was not forthcoming from all quarters in the earlier years, mainly because some enthusiastic promoters of voluntary infant welfare centers tried to convert them into miniature hospitals and endeavored to divert sick mothers and children from general medical practitioners and hospitals by means of solicitation through home visitors and by generous gifts of milk.

The legitimate sphere of infant welfare centers is educative, preventive, and advisory. This idea has now been generally accepted and acted upon by those in charge, and the good will of the medical profession and midwives is being secured.

THE CAUSES AND INCIDENCE OF INFANT MORTALITY

The principal causes of death in the first month of life are difficult labor, complications of confinement, birth injuries, maternal toxemia, syphilis, and premature birth. The two most important causes of death after the first month of life are respiratory diseases and gastroenteritis.

Of the deaths of children under 1 year, 40 to 45 per cent are due to difficult labor, injury at birth, prematurity, and developmental dis-

eases, while approximately 25 per cent are due to respiratory diseases (including whooping cough and measles), 10 to 15 per cent to gastroenteritis, and approximately 20 per cent to other causes.

A certain number of infant deaths are due to prenatal biological causes over which the maternity and child welfare service can exert no influence. For reasons not yet known, some pregnancies end in the birth of monstrosities, others terminate prematurely; in some pregnancies pathological changes occur which are sufficient to render the child incapable of survival. It has been found that there is a non-preventable infant mortality of 25 to 30 per 1,000 births, and these deaths occur almost entirely in the first month after birth.

But there is a wide sphere for maternity and child welfare work in eliminating adverse environmental factors which cause infant deaths. These arise before birth, at, and after birth, and include ignorance of the mother, malnutrition of the mother, defective sanitation, lack of skilled attendance, poverty, bad housing conditions, overcrowding, industrial employment of the mother, lack of breast-feeding, and atmospheric impurity due to smoke.

In England and Wales the infant mortality is higher in urban than in rural areas; it is much higher among illegitimate children; it varies, broadly speaking, with the density of the population; and it is higher among the industrial than among the other classes. Table I shows that the incidence falls chiefly on the first 3 months of life, especially the first 4 weeks.

The infant mortality rate remained practically stationary for many years before the present century, but during the last 30 years the decline has been considerable and continuous, as is shown in Table II.

TABLE I
DEATHS OF CHILDREN UNDER 1 YEAR PER 1,000 BIRTHS IN ENGLAND AND WALES

1926.....	70
1927.....	69
1928.....	65
1929.....	74
1930.....	60

In an impartial review of the situation, due regard must be paid to the contributory factors which have been at work side by side with the maternity and child welfare service. During and after the Great War the economic conditions of the working classes have been greatly improved, and in the post-war period there has been an increased and successful attack upon the "racial poisons"—alcohol, syphilis, and tubercle. The improvement in the midwifery service following the introduction of the Midwives Act of 1902 has been considerable. It is during the growth of the maternity and child welfare service that the community generally has enjoyed the benefits of the school medical service, established in 1907, and of National Health Insurance, inaugurated in 1912—the latter including maternity benefits for the insured.

The great sanitary improvement which has taken place in England and Wales had begun many years before maternity and child welfare services started; but in this connection it is fair to point out that although this factor had affected the general death rate in the latter half of the last century, it has only been during the period in which the maternity and child welfare work has been growing that the infant death rate has been falling.

Statistical data are open to widely different inferences and interpretations, but a careful survey has led to the general opinion that a considerable portion of the diminution in infant mortality can be ascribed to maternity and child welfare work of local authorities and the voluntary associations working in coöperation with them. Medical opinion supports this view entirely, but it is clearly impossible to determine the extent to which the credit for the diminution should be attributed to the various factors which have been operating.

A further reduction in the infant mortality rate can be made by securing additional improvements in the general sanitary environment, particularly in housing; by extending and improving the present ma-

ternity and child welfare schemes with a view to securing better education of mothers in the care and management of their children; by the provision of a domiciliary nursing service; by establishing improved coördination of the work of local authorities with that of private medical practitioners, midwives and general hospitals so as to secure effective prenatal supervision, adequate attendance at childbirth and such assistance as may be required to protect and safeguard the health of mothers and children after birth. Finally, and most important of all, much further improvement can be secured by the education of the community in all matters of public and personal hygiene. In this connection it should be pointed out that medical officers of health are anxious that maternity and child welfare work should not be divorced from other practical preventive work carried out under their supervision. They regard general preventive medicine as a developing service, of which maternity and child welfare work is a developing part.

MATERNAL MORTALITY

There are about 600,000 mothers in England and Wales giving birth to children each year. Of these, about 3,000 have died in each of the last 10 years in the fulfilment of this function. This is a serious and largely avoidable loss of life at the time of its highest capacity and in its most fruitful effort. Moreover, the deaths do not indicate the whole loss, for a much greater number than 3,000 are each year permanently injured or invalided in the physiological process of childbirth.

During the present century the general death rate for all persons at all ages has been reduced by approximately one-third, the infant mortality rate has been halved, and the death rate of women at reproductive ages from all causes has declined; but, as is shown in Table III, the maternal mortality rate has shown but little decrease in the last 20 years:

Puerperal sepsis accounts for the highest number of deaths; toxemia of pregnancy comes next; then hemorrhage; lastly, the various forms of disease concurrent with pregnancy or confinement may, either of themselves or by rendering confinement difficult, have fatal issues, among them being heart disease, pneumonia, rickets, syphilis and embolism.

The enormous interest aroused in this problem in recent years resulted in the government setting up a Maternal Mortality Committee, who have recently issued an important document incorporating the experience of a number of obstetricians and the results of a detailed study of 2,000 deaths of mothers in childbirth. The committee found that

TABLE III

Year	Births Registered	Deaths of Women Classed to Pregnancy and Childbearing			
		No. of Deaths	Rates per 1,000 Births Registered		
			Puerperal Sepsis	Other Causes	Total Mortality
					3.87
1911	881,138	3,413	1.43	2.44	3.98
1912	872,737	3,473	1.39	2.59	3.96
1913	881,890	3,492	1.26	2.70	4.17
1914	879,096	3,667	1.55	2.62	4.18
1915	814,614	3,408	1.47	2.71	4.12
1916	785,520	3,239	1.38	2.74	3.89
1917	668,346	2,598	1.31	2.58	3.79
1918	662,661	2,509	1.28	2.51	4.37
1919	692,438	3,028	1.67	2.70	4.33
1920	957,782	4,144	1.81	2.52	3.91
1921	848,814	3,322	1.38	2.53	3.81
1922	780,124	2,971	1.38	2.43	3.81
1923	758,131	2,892	1.30	2.51	3.90
1924	729,933	2,847	1.39	2.51	4.08
1925	710,582	2,900	1.56	2.52	4.12
1926	694,563	2,860	1.60	2.52	4.11
1927	654,172	2,690	1.57	2.54	4.42
1928	660,267	2,920	1.79	2.63	4.33
1929	643,673	2,787	1.80	2.53	

in 48 per cent of these there was an avoidable cause—an absence of antenatal care in 17 per cent, errors of judgment in practice or treatment by doctor or midwife in 17 per cent, negligence of the patient or her friends to adopt or carry out medical advice in 9 per cent, and lack of reasonable facilities for effective medical care in 5 per cent. In the remaining 52 per cent of deaths no preventable factor actually emerged, but the committee expressed the opinion that a fuller knowledge of the facts would probably have revealed such a factor in many, and that not less than half of these 2,000 deaths were avoidable.

HOW THE MATERNAL DEATH RATE MAY BE REDUCED

A study of the report of the Maternal Mortality Committee shows that, in order to secure a reduction of this high rate in England and Wales, there is a need for improvement in the education of the medical student in the principles and practice of obstetrics and gynecology. There is also room for improvement in the quality of medical practice. It is appreciated that doctors often work under a serious handicap in obstetric cases, but the investigation has shown the need for a higher standard of knowledge and skill on the part of medical practitioners, as well as for the provision of consultant services and of an increased

number of beds in maternity hospitals. Local authorities should improve and extend the facilities available at antenatal clinics. Every pregnant woman should have the advantage of effective antenatal supervision and a more intense effort must be made to educate and encourage mothers to use the facilities provided.

The committee recognized the immense progress made in recent years; but stated that there is still scope for further coördination of the maternity and child welfare services in every area, and formulated proposals for a national maternity service which may be summed up as follows:

1. The provision in every case of the services of a qualified midwife to act either as midwife or as maternity nurse.
2. The provision of a doctor to carry out antenatal and postnatal examination in every case, and to attend during pregnancy, labor and the puerperium, as may prove necessary, all cases showing any abnormality.
3. The provision of a consultant, when desired by the doctor in attendance, during pregnancy, labor and the puerperium.
4. The provision of hospital beds for such cases as need institutional care.
5. The provision of certain ancillary services, e.g., transport, sterilized equipment, laboratory facilities.

While the committee's report contains little which is original, it has brought together for the first time the various aspects of the problem. It has shown the channels along which future efforts should be directed. Briefly they are—improved antenatal supervision, improved obstetric practice, and more complete local organization to provide and make available all the necessary facilities for an effective service.

Evaluating the True Significance of Venereal Disease Morbidity

WALDEMAR E. COUTTS, M. D.

Chief of the Section for Social Hygiene, Santiago, Chile

THERE is no doubt whatever that efforts made by different countries of the world in combating venereal diseases have given good results, and we must believe what statistics show us in order to be satisfied. Notwithstanding this statement, a careful analysis of the morbidity coefficient obtained by reference to total population makes us believe that the decrease is more apparent than real.

The venereal disease morbidity coefficient for a determined period of time is calculated on the basis of the total census population or on that evaluated yearly by means of special equations. Let us suppose, for example, that during the year 1920 in "X," with a population of 5 million, 35,000 first infections of venereal diseases were registered—this would give us a 7 per cent morbidity for that year. The census of 1930 shows that the population of this same land has increased to 6 million, but the number of venereal disease contagions registered was more or less the same; nevertheless the morbidity would be 5.8 per cent.

We estimate that the error induced is larger if we take into consideration that the population which has raised the number from 5 to 6 millions is under puberty, and owing to this physiological reason, not exposed to a venereal contagion.

If we next think on the decrease of infant mortality, we will arrive at the conclusion that the estimation of venereal disease morbidity through simple calculation referred to total population does not give us a true knowledge of the real state of affairs.

On the other hand, we believe that there exists another factor which has contributed in a considerable degree to lower the number of venereal disease first contagions—the perfected methods of statistics which every day lessen the possibilities of reinscription and thus computation of a case two or more times.

With the system of identification card we keep in our dispensaries (24 in Chile), we are able frequently to prove that one man has abandoned one of them and sought treatment in another. With this

method such a patient will never be inscribed in our index as a new case of syphilis. Without this card one syphilitic appeared before as a primary case several times, and increased the statistics.

According to our opinion, the most accurate data for evaluating the efficiency of methods adopted toward preventing venereal disease contagion will be obtained when we modify our statistical methods in the way that we will try to prove.

In the vital statistics (demography) we find the most interesting data to establish our method. Starting from the total number of births in a given year, we can follow this mass of new-born through years until we arrive at the age at which we wish to start our study. For example, we start in the year X, in which 10,000 children were born. Of this total 8,000 reached their 15th year in the year Z. In the year X-1 12,000 children were born, of which only 9,000 reached in the year Z-1 their 15th birthday. If we then search the number of venereal disease contagions registered among boys of 15 years during Z and Z-1 years, we will be able to make a sound comparison (see illustrative table).

These groups can easily be followed yearly through statistics and we can keep a record of each successive annual group as regards ve-

Table for age 15 years

Year	Born	Death rate per year															Alive	Venereal Contagions	% in relation to living
		0-1	1-2	2-3	3-4	4-5	5-6	6-7	7-8	8-9	9-10	10-11	11-12	12-13	13-14	14-15			
1910	10000	600																	
1911	9000	720	350																
1912	12000	636	405	210															
1913			415	202	100														
1914				106	112	72													
1915					121	66	62												
1916						68	52	42											
1917							47	39	31										
1918								36	32	18									
1919									24	17	12								
1920										10	16	8							
1921											12	10	5						
1922												6	4	4					
1923													2	3	2				
1924														1	3	2	8484	325	38.3
1925															2	2	7317	285	38.9
1926																1	10123	425	40.

venereal disease contagion. If we allow 5 per cent error, which I esteem excessive, for emigration or immigration, I think we will always benefit largely by thinking of the advantages of basing our statistics on this method.

On the other hand, we can also group the total number of venereal infections in sections of 15-19 years, 20-24 years, etc., and make a series of combinations that will allow us to draw numerous interesting conclusions. Sex identification in all these series will afford us an inestimable means of relating these data to social development of communities, and of pointing out the most important sources of sensuality and exposure to contagion.

Clinics of Mental Hygiene, Milan

A RECENT decree issued by the government of the province of Milan provides for the establishment of 4 mental hygiene clinics in the city of Milan and 4 in other cities of that province. Additional clinics are to be opened as needed.

Their purposes will be: early diagnosis of mental disease; prevention of such disease through welfare work with persons showing abnormal tendencies; dispensary treatment combined with home visiting by a nurse; and financial aid and aid in kind when necessary. The clinics will be attached to the psychiatric hospital of Milan and maintained from public funds. Each clinic will employ a visiting nurse. The physicians at the clinic are required to instruct the patients in mental hygiene. The clinics are required to coöperate with the child welfare organizations and the various agencies interested in the protection of the people's health.—*La Medicina del Lavoro*, Milan, 1931, No. 8, p. 336.

Food Poisoning Following the Eating of Codfish Cakes

ELLIS KELLERT, M. D.

Ellis Hospital Laboratory, Schenectady, N. Y.

A GREAT variety of food products has been found to be associated with so-called food poisoning. In previous years, canned meats and vegetables, olives, cheese, and ice cream were the most common vehicles of transmission, and organisms of the salmonella, paratyphoid, enteritidis, and botulinus groups were most frequently isolated. More recently cake,¹ eggs,² cream fillings, and custard fillings have been identified with outbreaks of food poisoning.

Several years ago we learned of a case of gastroenteritis in which symptoms developed shortly after the eating of cake containing a cream filling. A piece of the cake regarded as the cause of the illness was examined bacteriologically and large numbers of *Staphylococcus aureus* were obtained. An investigation developed the fact that the baker who had prepared the cake suffered from boils of the forearms. That sickness may be induced by the eating of food contaminated by staphylococci is indicated by the studies of E. O. Jordan,³ who found that broth cultures of *Staphylococcus aureus* when taken by mouth produced gastrointestinal disturbance.

To the list of food products now occasionally identified with symptoms of poisoning we wish to add another—fish-cakes—the eating of which by several individuals resulted in illness with marked gastrointestinal symptoms.

On a warm Friday in June there was placed on an open counter in a public market a tray holding several dozen codfish cakes. Purchases were made by several women in the morning and eaten at noon. In each family which ate of them gastrointestinal symptoms developed and in 2 the symptoms were identical and severe. The history of one is as follows:

Codfish cakes bought at 11:30 A.M. were eaten at noon by the mother and 3 sons. At 8 P.M. the mother developed fever, abdominal cramps, vomiting, diarrhea, and was prostrated. The 3 boys also became sick that night with identical symptoms. The father of the

family did not eat the fish-cakes and remained well. The mother and sons were ill for about a week, but recovered.

A piece of codfish cake was obtained on the following day by the attending physician, and brought to the laboratory in waxed paper which was part of the original wrapper. We found in smears of the fish-cake numerous Gram-positive cocci and Gram-negative bacilli. Cultures on blood-agar plates yielded many colonies of streptococci of the viridans type, and a Gram-negative bacillus, which exhibited the following characteristics:

A slender non-motile bacillus producing on Endo's medium colorless colonies about 1 mm. in diameter with granular surfaces. Veining and slightly scalloped margins were present. On triple sugar medium, the butt showed acid production; the slant remained colorless, and there was no gas production. Litmus milk became faintly acid; gas was not formed in lactose broth, nor in the various carbohydrate media. In dextrose, maltose, mannite, levulose and galactose, acid was formed but none in saccharose or dextrin, and only in lactose on prolonged incubation. Indol failed to develop in peptone broth.

The organism was not agglutinated by typhoid serum or by dysentery serum, Shiga. Indefinite agglutination was obtained with polyvalent serum. A guinea pig injected intraperitoneally and a rabbit intravenously with a 48-hour broth culture both developed frequent bowel movements and loss of appetite but soon returned to normal.

The organism seemed to be an atypical strain of *B. dysenteriae* and a culture was submitted to Marion B. Coleman of the Division of Laboratories, Department of Health, State of New York, who reported the organism to be *B. dysenteriae* Sonne.

The circumstances in this small outbreak of food poisoning make it appear very probable that the codfish cakes were responsible for the symptoms. The *B. dysenteriae* is not commonly associated with food poisoning although Gilbert and Coleman⁴ found it rather frequently in specimens of feces obtained in New York State, and suggest that this strain of *B. dysenteriae* may be more prevalent than has been supposed. Since the organism develops a soluble exotoxin which is readily absorbed by the intestine it is not unlikely that many common foods may become contaminated by this strain of *B. dysenteriae* and when eaten give rise to symptoms of food poisoning.

Work Environment as a Factor in the General Health of Workers*

BERNARD J. NEWMAN, F. A. P. H. A.

*Director, Philadelphia Housing Association; Formerly, Consulting Hygienist,
Office of Industrial Hygiene and Sanitation, U. S. Public Health Service*

IN discussing the influence of work environment on the health of industrial workers, we are concerned primarily with the predisposing causes of disease; not with the exciting causes. Adverse work environment, including bad housing, is not, of course, a disease in itself. One cannot subject it to microscopic examination and isolate a pathogenic bacillus to which a name may be given. It cannot be subjected to laboratory analysis to determine its chemical constituency, nor can one so label it in the nomenclature of causes of death that the physician may incorporate it on his death certificate. Nevertheless, this does not minimize the importance of the problem since the predisposing causes of which it is one are often as great a menace as the organisms of disease, or the industrial poisons that destroy cell life and inhibit the normal functioning of the body organs.

To the industrial hygienist this may seem trite. Gifted with an inquisitive mind, he seeks and finds causes for industrial diseases not only in the chemical and physical properties of the elements and compounds handled in industrial processes but also in the faulty hygiene of the worker and of the workplace. That he can reduce the frequency and severity of industrial diseases through improved plant practices demonstrates that often the serious aspects of such operations are not the materials themselves so much as the way they are handled. Some processes are always potential hazards, but by means of plant or personal hygiene the danger from them may be reduced or eliminated.

If the hygienist limited his research to the demonstration of a specific compound as the exciting cause of an industrial disease, very little progress in the maintenance of industrial health would be made. Because health research in industry recognizes the part played by working conditions and the work habits of the industrial worker, and institutes plant improvement programs directed against them, progress in industrial health has been rapid.

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

Out of such recognition of working conditions as causal factors in industrial sickness have come definite programs to eliminate defects in plant sanitation, faulty illumination, excessive temperatures, insufficient or excessive humidity, excessive noise, monotonous or heavy labor responsible for excessive fatigue, overcrowding of work rooms, and faulty employment practices that create irritating human relationships and wrong mental attitudes among workers toward plant management.

Thus, from the known hazard attendant on the use in the plant of poisonous compounds, designated here as the exciting causes, and the known influence of adverse plant conditions, designated here as contributing causes, the hygienist is able to develop a preventive program which reduces the incidence of industrial diseases. The question here is, does he go far enough in determining all the factors that affect the health of the worker and so influence his efficiency as a producer?

The primary function of the hygienist, whether in research or counsel to the plant management, is to evaluate every major factor that has a bearing on the health of the worker or that increases his susceptibility to disease whether of a communicable, degenerative, or industrial nature. Only as his analysis is comprehensive can he state specifically the responsibility of any set of causes. This is not an academic judgment, since the comprehensiveness of his knowledge and the programs based upon it affect alike the practicality of the measures he recommends to the plant and the thoroughness of the protection he gives to the worker. Moreover, in so far as he tries to approach his problem as a scientist, he must include in his research every major field influencing the health of the workers. The line of demarcation of his analysis cannot scientifically be the plant boundary; it must necessarily be advanced beyond this to include the home environment of the worker and the factors there which have a tendency to lower body resistance or increase susceptibility to any disease.

This is conspicuously exemplified in the study of fatigue. The predisposing causes recognized by the hygienist as being associated with certain plant processes or conditions which induce excessive fatigue are not always of plant origin. Indeed, much of the so-called "industrial fatigue" does not arise within the plant, though often so credited, but is a compound of plant activities and home or other environmental conditions which deny to the worker adequate rest. Thus, overcrowded neighborhoods, congested sleeping quarters, poor ventilation with excessive temperatures, all tend to prevent normal rest and deny the recuperation which should follow a day's toil. There is thus produced a cumulative effect from industrial fatigue and disturbed rest which leaves the worker more susceptible to adverse working conditions and processes.

Other non-hygienic home conditions produce results similar to those associated with adverse plant conditions. Moreover, the de-energizing effect of depressive environment has many physical and mental complications which cannot be overlooked. Needless to say, any program for the maintenance of industrial health which concentrates on environment within the plant, and disregards the homes of workers outside, renders the employer a restricted and oftentimes misleading service. It cannot but dub the hygienist as a pseudo-scientist.

To anyone with only a casual knowledge of the housing field these comments may seem unwarranted strictures. It may be alleged that the industrial worker's home is the same type as the average home of the community, and thus its defects should be the concern of the public health department. It may be claimed that lack of a pure water supply, of sanitary equipment or of sanitary sewage and waste disposal, overcrowding, abnormal or subnormal temperatures in certain types of homes, caches of filth and vermin, are the community's obligation, with industry absolved from all responsibility except as its managers are citizens. The industrial hygienist may likewise believe his responsibility is only social and not professional—although his greater knowledge of the consequences of unsanitary conditions should make this interest somewhat keener—and that his sphere of research is restricted to the determination of plant health hazards.

To one who has specialized in both housing and industrial hygiene this attitude seems grossly unscientific. The scientific mind is the searching mind. It is looking for causes. It does not limit its field of research, if by so doing it stays its search short of knowing all the factors that may affect the results. This does not mean that in research into lead poisoning one must initiate a housing program. It does mean that if we ignore the influences of the homes we may mistakenly conclude that certain processes are non-hazardous because we may have a large percentage of employees who live under conditions that help to maintain their physical condition and are therefore less susceptible to special hazards.

The reverse may be true. There is a tendency to blame the plant when the substandard home is equally at fault. The high incidence of special diseases in some industrial plants may be due to the low physical resistance of the workers because they are exposed during non-working hours to slum living conditions. Personal hygiene and certain habits that we associate with predisposing causes are included in our schedules of physical examinations; plant conditions are considered, but living conditions have received only cursory attention. This seems absurd, but it is true. Consequently, the effect of the

work environment outside the plant is not emphasized and any interest displayed in the workers' living conditions is on an emotional basis rather than because the managers consider it good business to assist their employees to attain wholesome homes. Unfortunately, this is the least satisfactory basis for sustained, constructive interest. Yet today in the United States the health hazards to industrial workers which arise from home environment constitute a major problem. The worker is heavily handicapped, his earning capacity reduced, and the employer unnecessarily burdened with added production costs. There is a trend in our cities toward decentralization, in part induced by tax burdens but largely because the labor supply is substandard. Factories are moving to the country where they can find relief from these cost-increasing factors. Any brief survey of urban conditions is sufficient to demonstrate the prevalence of substandard housing in areas where wage earners live.

The characteristic defects of such areas are conspicuous: congested buildings, often of the multiple type of occupancy; room overcrowding; a high percentage of families occupying apartments of 1 and 2 rooms and often living in basements, cellars and back lot houses; insufficient natural light and substandard artificial light; excessive temperatures; inadequate sanitary equipment; insanitary drainage; widespread prevalence of filth both within and without the dwellings; unsafe structures; insufficient play space for children; street hazards; widespread nuisances in the form of defective plumbing, flooded cellars, and damp rooms; general drabness and deterioration of whole neighborhoods which exerts a depressing effect upon the population. Ten per cent of the workers of the country are exposed to some or all of these conditions, nor are they limited to large urban centers although they are more conspicuous there due to segregation. Even the smaller cities and villages have their areas of substandard dwellings and subnormal living.

It is not true, as some imagine, that the slums house only the day laborer. They provide quarters for the so-called skilled-trades workers as well. Throughout the country, these blighted areas are inducing an irregular manner of living; they are furnishing a large percentage of the causes for the spread of communicable diseases; are undermining public health; and in a measure are responsible for the accelerated fatality of the degenerative diseases.

The criticism of the existence of such areas cannot be refuted on the grounds that the inhabitants are content with their homes. There is no justification for inactivity in the belief that such persons, if given good housing, would continue in the manner of living from which they

had been removed. Even if this statement, which is false in 90 per cent of the cases, were true, it would be no answer to the problem presented by these individuals and their homes. Their threat to society alone would justify any amount of attention to housing betterment; but our interest is not in the general menace of existing conditions but rather in their specific handicap to efficient labor, because industry is frequently falsely accused of maintaining hazardous working conditions producing disease and ill-health, when actually the situation is complicated and accentuated by the insanitary state of the homes the workers occupy.

The statistical records prove that occupants of substandard houses and areas show abnormally high morbidity and mortality rates, high percentages of physically unfit workers, many lacking the right mental attitude or intelligence to accomplish the work assigned to them in the plant or to stabilize their employment by continuing their jobs under normal conditions. In times of slack employment, the workers with poor environmental conditions are the first to be laid off, but in times of normal business they must be employed because they constitute the only extra labor supply available. When employed, they contribute a high rate of absenteeism on account of sickness, and cause a costly labor turnover which affects production costs.

Because of the prevalence of adverse living conditions and their reaction upon the physical and mental health of workers, the industrial hygienist must, if he is to do scientific research, carry his studies beyond the plant boundaries, and furthermore if he is to advise the plant management wisely, he must emphasize the disadvantage of such adverse living conditions to industrial workers. Housing specialists do not characterize bad housing as an exciting cause of disease but they do emphatically believe that it is a predisposing cause, which is relatively as important in the final physical breakdown as many exciting causes more frequently emphasized.

The object of this analysis of the health of industrial workers is to assure due valuation of the contributing part played by environmental factors on the one hand, and on the other, to call the attention of plant managers to an aspect of their problem which has been generally neglected. Industry is not to be encouraged to finance housing schemes, but it should formulate a program which will assure the elimination of bad environmental conditions for employees.

Industry does not need to build towns or model dwellings for its workers in order to insure adequate standards of living. It can exert its influence on safe, wholesome living conditions by establishing and giving adequate publicity to an employment policy which gives pref-

erence to those workers who have shown, or will show, an intelligent self-interest in avoiding the occupancy of substandard dwellings or areas.

Where the supply of sanitary houses is adequate but the business judgment of the worker poor, industry can promote thrift associations such as building and loan societies to facilitate home ownership; where the supply within the buying or renting ability of its employees is insufficient, industry can, by means well within its sphere of interest, encourage builders to erect new houses, and urge owners to recondition those old houses which are within a reasonable distance from the plant. If the situation is chronic, as it is in large urban centers, plants can be moved to suburban areas or to smaller towns where more normal living conditions will be assured.

It is not our purpose here to outline and define industry's program for adequate housing of employees so much as to indicate that a reasonably selfish interest dictates a recognition of the part played in economic organization by insanitary housing. Good judgment necessitates the inclusion of housing data in analyses of the hazards of industry, and, in the event that a causal relationship is found between environmental conditions and the diseases they are studying, these findings should be emphasized so that plant managers will feel it incumbent upon them to develop a program adequate to meet the situation.

The Response to the Appeal for Blood for Treatment of Poliomyelitis

OVER 1,100 persons responded to the appeal of the State Department of Health for donors of human immune blood for use in the treatment of cases of poliomyelitis. Actually 1,011 persons were bled between July 27 and October 5, exclusive of the 31 patients at the Georgia Warm Springs Foundation who contributed their blood. In addition, 87 persons were bled twice and many other donors volunteered to be bled a second time. A long and growing list of later volunteers is held in reserve at the State Laboratory. Fifty of the 57 counties in the state outside of Greater New York are represented by at least one donor each. The record is interesting and gratifying from both the administrative and public health standpoints and also as a fine example of immediate state-wide response by individuals to an emergency health appeal.—*Health News*, New York State Dept. of Health, Oct. 26, 1931.

THE CONGRESSIONAL AWARD TO THE YELLOW FEVER COMMISSION

THE award of medals by Congress to the Army Medical Commission, which cleared up the etiology of yellow fever—Dr. Walter Reed, Chairman, Dr. James Carroll, Dr. Jesse W. Lazear, and Dr. Aristides Agramonte—and to those who took part in the experimental work by offering themselves as subjects and otherwise, calls for more than passing comment.

This Commission was appointed in 1900. Agramonte and Lazear were already in Cuba, and Reed and Carroll joined them in Havana in June of that year. So rapid was their accomplishment that at the 29th annual meeting of the American Public Health Association held in Indianapolis, Reed was able to give a paper called "The Etiology of Yellow Fever—A Preliminary Note," and the *Philadelphia Medical Journal* gave an article on the same subject in its issue of October 27, 1900. On the night of December 31, with only a few minutes of the old year remaining, Reed wrote to his wife, "The prayer that has been mine for twenty years, that I might be permitted in some way or at some time to do something to alleviate human suffering, has been granted! A thousand Happy New Years." Other publications followed rapidly. On February 16, 1901, the *Journal of the American Medical Association* published the article read by Reed before the Pan-American Medical Congress in Havana during that month.

Such is in brief an outline of one of the most remarkable pieces of medical work which the century has seen—one which has saved tens of thousands of lives and tens of millions of dollars. Curiously enough, it excited little interest outside of medical circles. The U. S. Government, which profited vastly by the discovery, took practically no notice of it, and even our universities did scant honor to the men who had carried out this magnificent piece of research at the danger of their lives, one of them indeed having succumbed to the disease, and a second having been desperately ill of it during the work. In 1902, Harvard University conferred the honorary degree of Master of Arts on Reed, and the University of Michigan the degree of LL.D. As early as 1903 an association was formed with the object of calling attention to Reed's work and establishing a memorial. Its work finally took the form of an attempt to raise a fund of \$25,000, the income to go to Mrs. Reed and her daughter during their lives, the principal to be applied to the erection of a monument to Reed, or the promotion of research in his especial field. A number of articles were published urging such recognition, and individuals worked to the best of their ability, with little or no effect. The proverbial ingratitude of republics left the work of Reed and the Commission, as well as the devotion of the noble persons who lent themselves to the dangerous work without recompense, practically unnoticed officially. Finally some 30 years later, Congress voted the award of gold medals to the Commission and to 18 soldiers and others who had taken part in the work. These medals were sent during the first week of October, 1931, to the survivors and heirs, since, alas, many of the original workers had passed on. It may seem a bit ungracious at this time to call attention to the neglect of Reed, his medical coworkers, and others. It is true that all are now delighted at this recognition, late though it comes, and one is

inclined to be a bit cynical over the value of a medal to the families of the dead. On the other hand, we rejoice that our government has at last been awakened to the importance of scientific work, even though late. Had this work been done by an Englishman or Frenchman, for example, the awards would have been prompt and abundant. Jenner, the discoverer of vaccination, received grants amounting to £30,000, and an additional £7,383 from subscriptions in India. Lister was knighted and elevated to the peerage. Pasteur received from the French government a pension of 12,000 francs annually, and many other instances might be cited.

The last surviving member of the Commission, Aristides Agramonte, died in September of this year while in New Orleans preparing to assume his duties as Professor of Tropical Medicine. Lazear died of yellow fever during the work. Reed and Carroll have been dead for approximately 25 years. Some of those who lent themselves for experimental purposes have been in bad health and dire need. One cannot help thinking that it would have been much better to have given these men recognition in the shape of even small pensions than to send gold medals to those who have survived and to the heirs of those who are dead.

THE HEALTH OF PORTO RICAN CHILDREN

THE sanitary problems of one section of the United States may be and generally are of direct significance to the people of all other parts of the country, no matter how distant. Although disease is sometimes influenced by geographical considerations, it is seldom hindered by political barriers, and practically never by social or economic boundaries. National health is more difficult to visualize than

is community hygiene, but it is just as important to every citizen of the nation.

Porto Rico and its distressing health conditions may seem remote to most of us; but this West Indian island has been part of the United States for a third of a century, and its million and a half inhabitants are as much American citizens as the Mayflower descendants of Massachusetts, or the cosmopolitan residents of East St. Louis. A committee of the American Child Health Association¹ has pointed out that ignorance and poverty, and their inevitable concomitants, sickness, disease, and undernourishment, are excessively prevalent on this attractive tropical island. The crude death rate in Porto Rico is nearly double that in the United States, and infant mortality, that sensitive index of sanitary progress, is almost 3 times as high.

According to our standards of age distribution, Porto Rico has about 175,000 children too many. Despite unfavorable economic conditions, the birth rate is estimated to be over 40 per 1,000, and the census of 1920 recorded the amazing fact that 43.3 per cent of the population was under 14 years of age. Contrast this with 31.7 per cent in the United States, according to the figures of the same census. Tuberculosis, hookworm, malaria, and malnutrition are, next to the abnormal infant mortality, the most serious of the health problems of Porto Rico. Tuberculosis is literally epidemic, with a death rate over 300 per 100,000 population, while malaria and hookworm are endemic. Although the first scientific research which led to the recognition of the American necator was done more than 30 years ago in Porto Rico by Captain Bailey K. Ashford of the U. S. Army Medical Corps,² hookworm has never been extirpated from Porto Rico and, according to the investigators, will not be until the inauguration of full-time health service for the entire island.

Malnutrition is ubiquitous in Porto Rico. Sherman³ states that provision of milk for the children of the island may well take rank as a public health measure along with the hospitalization of open cases of tuberculosis, the field work against hookworm and malaria, and the laboratory studies of intestinal diseases. Since the milk supply is inadequate, the solution of this urgent problem lies in the liberal use of American canned milks. Already, many of the official child welfare stations are supplied with powdered whole milk and where this has been employed, gratifying reductions in infant mortality and improvement in child health have been obtained.

Because of an abundance of sunlight, rickets is rare, although calcium intake is low. Sherman believes that the low calcium and low vitamin A content in the diets of these children probably tends to make

them less resistant to tuberculosis. Anthropometric measurements by Mitchell¹ indicate, moreover, that diet and disease have definitely influenced the stature of Porto Rican children.

Although children of the better socio-economic classes were found to have larger skeletal frame and musculature and greater amounts of subcutaneous tissue than the less privileged groups, dental caries was more abundant in the former class than in the latter. The tendency to dental caries among Porto Rican children operates, in fact, in a reverse manner from what would be expected and as has been the experience in the United States. This strange finding seems inexplicable and the only attempt to explain it is that there is some obscure influence favoring immunity to dental caries which only further study can reveal.

This notable report on child health in Porto Rico contains much that is provocative in the realm of medical science. Not only is it a noteworthy contribution to modern public health, but it raises sociological, economic, and even governmental questions of vast importance. Should one section of the United States be permitted to suffer continuous ill-health when others are favored with skillful attention which serves to reduce death rates and render life longer and more enjoyable? Physical and mental health is conceded to be one of our greatest national assets. Desirable improvement in physical vitality should be the privilege of every American citizen and particularly of those who are to be the citizens of the future.

PUBLIC HEALTH ADMINISTRATION

Diphtheria in Bridgeport--Diphtheria had been extensively present in this city for 50 years until a new administrative program was put into effect by the Health Department in March, 1928. Prior to that date release was made on one negative culture from the nose and throat on two successive days. Subsequent to November, 1928, release has been made by multiple negative cultures from the nose and throat on two successive days, and the number of contacts to be cultured has been extended to include all women and children living under the same roof with the patient and likewise the fathers of patients or carriers. Fathers of contacts are examined only when they are food handlers. If a case occurs in a school child all members of the particular class involved are cultured.

A diphtheria immunization program was begun in 1926 and has resulted in the immunization of 51.2 per cent of the school children and about 26 per cent of the preschool group. The authors feel, however, that the immunization treatments have been no more important in the reduction of diphtheria in Bridgeport than the administrative measures established in 1928 which included briefly the release on multiple cultures, bacteriological examination of every possible contact, and the use of Loeffler's fresh blood serum, with or without chloroform, as a medium.—William F. Wild and Kathryn R. Tirrell, *Diphtheria Control in Bridgeport, Conn.*, *J. Prev. Med.*, 5, 303 (Sept.), 1931.

Typhoid in Richmond County—Richmond County is rural, with 35,000 people, two-thirds of whom are colored, and is situated on the southern border

of North Carolina near Pinhurst. A County Health Department was organized in November, 1924. During the 9 years prior to 1927 there was an average of 23 cases of typhoid reported yearly, while for the 3 years 1927-1929 the average was 5.3 cases per year.

Particular emphasis has been placed upon health education. An effort has been made to stimulate response from the negroes by approaching this group through their clergy. Results have been most promising and in addition to immunizations against typhoid fever, there were in the first 6 months of 1929, 1,500 protective treatments given against diphtheria among colored children. Smallpox vaccination has also been a by-product of the educational campaign. The authors feel that the greater percentage of the decrease in typhoid has been due to better methods of sewage disposal, especially in the towns of the county, where proper sewage facilities have been installed. North Carolina has a state-wide sanitary privy law which provides that a householder is not permitted to have any type of privy or system of sewage disposal within a mile of any municipality that has not been approved by the State Board of Health. Word of mouth information in the uneducated public has done much to cut down the typhoid fever death rate.—The Control of Typhoid Fever in Richmond County, N. C., A. B. McCreary, *J. A. M. A.*, 97, 998 (Oct. 3), 1931.

Relief in Tuberculosis in Syracuse—It is estimated that Syracuse spends annually about \$332,000 in its health and relief services for tuberculosis, of which sum 85 per cent is expended in health services and 15 per cent in re-

lief. Involved in this study were 1,288 tuberculous families known to the Health Department on May 1, 1929, of which number 296 families were classified as economically secure and therefore eliminated from the study. The remaining 992 families were divided into two groups, those who had received relief and those who had not but who had availed themselves of the free health or social services of the community. There were 211 families who had received relief and 781 in the second group. A survey was made of 34 families selected at random from the first group and 36 families from the second group. The conclusion is reached from the samplings made that most of the 781 families in the no-relief group were able to maintain an adequate standard of living. However, there is indication that about 80 of the families in this group were in need of relief. Among the 212 families who had received relief, it was found that in 150 instances the relief given was inadequate.

The general conclusion is that social service and relief in tuberculosis are on the whole totally inadequate to the requirements of the situation and most communities have developed their medical facilities for dealing with tuberculosis more adequately than their social facilities.—Bailey B. Burritt, Social Service and Relief in Tuberculous Families, *Quart. Bull.*, Milbank Memorial Fund, Oct., 1930.

Meningitis in Detroit—In the course of an outbreak of meningococcus meningitis, 6,416 home contacts of 1,272 meningococcus meningitis patients were examined and 685 carriers found among these contacts. There were also examined 1,991 persons not known to have been in contact with a meningitis patient and 19 of these were found to be carriers. The authors conclude that the relative frequency of home-contact

carriers cannot be used as a basis for predicting the termination of an epidemic. There was no evidence for either sex of a greater tendency to become carriers. The percentage of carriers among children between 1 and 10 years of age was slightly greater than among older children or adults and the lowest carrier rate was found among infants.

Of the contact carrier 27.6 per cent had meningococci in the nasal pharynx when they were released at the end of a 2-week quarantine period. Of the contact carriers released as negative before the termination of quarantine, 36.6 per cent cleared up within 3 days, 32.3 per cent between the 4th and 6th days, 21.1 per cent between the 7th and 9th days, and 10 per cent between the 10th and 14th days. There is no record of any of the persistent carriers having contracted meningitis. It is essential to make more than one examination to detect the carrier state. In this study 30 per cent of carriers located would have been missed if only one culture had been taken.—Meningococcus Meningitis in Detroit in 1928-1929, J. F. Norton and Irene Baisley, *J. Prev. Med.*, 5, 357 (Sept.), 1931.

Diphtheria Carriers—In Baltimore a study has been made of 3,449 individuals who have been exposed to diphtheria and cultured on the report of the primary case. Of this number 11.7 per cent were found to be positive on morphological diagnosis. There were more carriers among contacts under 10 years of age. Of 348 persons positive on primary culture and cultured again usually after an interval of 10 days, 44 per cent were positive. Among 1,971 individuals negative on primary culture, after 10 days 13.4 per cent were carriers. The total found positive in either primary or later cultures was 31.3 per cent for those under 9 years of age, 20.8 per cent for those 10 to 19

years old, and 19.6 per cent for those under 20 years of age. Examination of sample cultures showed 57.5 per cent of carriers to have virulent bacilli. The total virulent carrier rate for both primary and release cultures was 13.1 per cent.—Y. Kusama and J. A. Doull, Carrier Infection Among Family Associates of Diphtheria Patients, *J. Prev. Med.*, 5: 369 (Sept.), 1931.

Connecticut—The 1930 Department of Health report of Connecticut directs attention to the provision in many states whereby financial aid is available for the formation of district health departments, and indicates that such aid for the smaller towns of the state is desirable and necessary for the success of the district health department idea. Such aid could be furnished on the same basis as is state aid for public health nursing already provided.

During the year the health of the state was reported good, and the general death rate was 11.1, the second lowest in the history of the state. Plans have been perfected for a new building to house the department. An encouraging outlook in diphtheria is reported. Each mother to whom a birth certificate is sent is notified at the same time, and again when the child is 6 months of age, to have the child immunized against diphtheria. Many of the departments of health in the larger cities are doing likewise. Tularemia and undulant fever were made reportable diseases in 1928 and since that time the latter disease is being increasingly reported.

Good progress is reported in the institution of generalized public health nursing service, and there are now 100 towns and cities in the state reported as having such a service. An outstanding event in mental hygiene was an institute carried out for 3 weeks by the State Department of Health with the coöperation of the Connecticut College

for Women, the Connecticut Society for Mental Hygiene, the Hartley-Salmon clinic and numerous outside agencies that contributed personnel and aid toward its success.

In the laboratory there was a 12 per cent increase in examinations over the previous year. The division of occupational diseases reported 81 surveys and 25 studies of particular conditions carried on in coöperation with industries. The division of public health instruction notes among other activities 399 lectures by the personnel of the department, and 27 radio broadcastings, during the year.

Wood County, W. Va.—In the annual report for the fiscal year ending June 30, 1931, attention is called to health problems resulting from the severe drought, including the failure of water supplies which affected quantity and quality of many sources. The business depression is considered a causal factor in lowering the resistance of the people. Expenditures of this combined health unit last year amounted to \$12,000. A budget of 5 times this amount is suggested as desirable in a comprehensive plan of public health administration outlined in the report. Sir Lauder Benton is quoted on the opening page as follows:

Like other natural laws, the laws of health are inerrant; ignorance of the laws is not admitted as an excuse any more than motives; and the sentence for breaches is true now as it was ages ago. The soul that sinneth it shall die.

An epidemiological study of tularemia was made during the year, as several cases transmitted to man by handling of diseased rabbits occurred. This was made a reportable disease.

The county is fast becoming highly protected against diphtheria. Complete toxin-antitoxin administrations numbered 1,789; smallpox vaccinations, 808; and antityphoid inoculations,

2,162. There were 45 baby clinics held under the sponsorship of the Junior League with an attendance of 1,259.

We expect fire protection, good roads and an efficient educational system. We pay for these and we do this in a coöperative way. We must have an arousing of the health desire and buy it as we buy all commodities. Individual home owners must pool resources and go after this improvement as a group. Rudyard Kipling in a celebrated stanza has expressed the value of coöperation in accomplishing a desire:

For this is the law of the jungle,
As old and as true as the sky;
The wolf that shall keep it will prosper,
The wolf that shall break it must die.
As the ivy entwineth the tree trunks,
The law weaveth forward and back;
The strength of the Pack is the wolf,
And the strength of the Wolf is the Pack."

Winnipeg, Man.—On the basis of a population of 209,286, a corrected death rate of 7.6 per 1,000 population is reported for 1930. An infant mortality rate of 57.9 is noted. Attention is called to the epidemic index for diphtheria, which shows a decline continuing below the line of normal expectancy. The preventive work in schools and institutions is believed, in some measure, responsible for the lowering of the rates. There were 231 cases of pulmonary tuberculosis reported with 97 deaths, giving a corrected mortality rate from this disease of 51.6.

It is satisfactory to record that a larger proportion of the milk supply is being pasteurized from year to year. "We still regard this procedure as the greatest safeguard that can be adopted to protect the milk supply of a community."

Under legislation there is noted an amendment to the Public Health Act defining "maternity home" as a building where a woman or girl may be treated during pregnancy or accouchement, and providing that the department of health and public welfare may make rules regulating the management and conduct of child-caring institutions, maternity homes, and other institutions caring for patients, and cancel their permits on failure to comply with such rules.

Rhode Island—The first biennial report of the State Public Health Commission covers the years 1929-1930. Immunization of school children against diphtheria, begun in 1922, has been continued. A decrease in diphtheria death rate to less than half of what it was for the 5-year period before the work started is reported. But analysis of the records shows that over half the deaths from diphtheria occur under the age of 5 years. To reach the preschool child, the Division of Child Hygiene has arranged for immunization in preschool clinics. Emphasis is given in the report to the desirability of full-time health units.

A general death rate of 11.6, on the basis of a 1930 population of 689,524, is recorded, with a birth rate of 17.5. Infant mortality has been reduced over 60 per cent since 1900, the rate for the period 1925-1929 being 71.6. This report has been carefully prepared and contains much information regarding legislation and bureau activities under the newly organized public health commission.

LABORATORY

ANTIGENS IN THE WIDAL TEST

GRACE ELDERING AND NEWTON W. LARKUM, PH. D.

Michigan Department of Health, Lansing, Mich.

PUBLIC health laboratory procedures must of necessity be standardized within certain limits, and as a consequence change is difficult and slow. This is well illustrated in the case of typhoid fever where the Widal test, recognized as the most useful diagnostic measure, has been carried on in the same manner for 30 years in spite of significant discoveries which, although amply verified, are still awaiting general adoption. A consideration of these contributions and the possibility of their inclusion in routine testing is the basis for the following study.

The recognition of the existence of dual antigens in many bacteria, first demonstrated by Weil and Felix,¹ has led to a material accumulation of knowledge on the antigenic nature of bacteria, and the studies in microbic variation have helped to hasten the day when laboratory workers in general might recognize that the supposedly specific antigens used in diagnostic tests and in the production of immunity were specific only within certain limits. The practical value of these investigations has apparently been appreciated in Great Britain more quickly than it has in the United States, and the recent summary of Topley and others² constitutes a challenge to the American laboratories.

Many bacteria, those of the enteric group in particular, have been shown to contain two antigens, one heat stable,

called the "O" antigen, the other heat labile, called the "H" antigen. The "O" antigen is generally conceded to be somatic in origin, the "H" antigen on the other hand is probably resident in the flagellar material. Under different conditions of growth the proportion of the two antigens will vary so that it occasionally happens that some strains will contain only pure "O" antigen. It is scarcely conceivable that an organism could consist entirely of "H" antigen, yet there are strains that contain a very high proportion of the flagellar substance.

Immunization with cultures having varying proportions of the two antigens results in serums having antibodies reacting with different degrees of intensity with each antigen, and this occurs whether the immunization is caused by an attack of the disease or by deliberate inoculation. In the test usually employed (agglutination) for the recognition of antibodies under these conditions, there is an easy and dependable method for distinguishing between the two types of response. The differences in the two types of agglutination are given in Table I.

In spite of this description, however, the recognition of the two types of agglutination is not always easy until the worker has actually seen suspensions of the two types. The British Medical Research Council has prepared suspensions of these two types, samples of

TABLE I.

"O" agglutination
granular
forms slowly
settles slowly
flakes small and uniform in size
supernatant fluid clear
sediment scanty and difficult to dislodge
"H" agglutination
flocculent
forms rapidly
settles rapidly
flakes large and varying in size
supernatant fluid cloudy
sediment voluminous and easily dislodged

which were sent to us through the kindness of Dr. W. W. C. Topley and Dr. A. D. Gardner. With these suspensions and their agglutinating serums, we were able to determine the type of antigen in routine use in our laboratory and to study serums sent in for diagnosis. The technical details follow:

1. *Preparation of Antigens*—Veal infusion broth, pH 7.48, was inoculated with Felix's typhoid strains, "O" 901 and "H" 901, incubated at 37° for about 20 hours, and killed with 0.2 per cent formalin. The suspensions were diluted with saline to conform in turbidity with the standard received. In character of agglutination the "O" compared very well with that prepared by the Lister Institute, but the "H" yielded clumping very similar to the "O." After several attempts to produce an "H" antigen with this culture, we gave it up. Our own antigen used routinely gave a very pretty flocculent agglutination. As it seemed

probable that the "O" was the antigenic factor that was added in the new technic, we decided to use only this in comparison with our routine test. The antigen used in this routine procedure is a saline suspension of organisms to which 0.1 per cent formalin is added.

2. *Serum dilutions*—Serum dilutions for the tests were from 1:40 to 1:640, or higher.

3. *Incubation*—Reading was made after 2 hours' incubation at 56° in a water bath. Final reading was made when the tests had stood overnight at room or icebox temperature. The 2-hour period is considered long enough to allow the "H" agglutination to occur, but we were advised that the test with the "O" suspension should not be read until it had incubated 4 hours, and that a longer period of 16 to 20 hours at 56° was necessary before final reading could be made. It was our experience that whether the tests were left at icebox, room, or water bath temperature after the primary incubation was immaterial, but that significant agglutination of the finely granular "O" type did occur during this added period.

4. *Reading*—We were advised to make readings by artificial light, or, if by daylight, to pass a finger up and down behind the tube. Our readings were made by daylight, and to the highest dilution showing clumps just visible to the naked eye.

The typhoid 703 is the strain used in the preparation of our diagnostic antigens. From Table II it will be seen that although our antigen contains both "O" and "H" antigen, it is more rich in the "H" fraction and hence is not satisfactory for determining the type of agglutination present in a given serum.

Using our regular antigen (703) and

TABLE II
COMPARISON OF OUR ANTIGENS AND SERUMS WITH THOSE OF THE LISTER INSTITUTE

Serum	Antigen	Agglutination
Our typhoid strain 706	Our typhoid strain 703	1:20,480 (flocculent) (titer not determined)
Our typhoid strain 706	Lister Institute "O"	1:1,280 (granular)
Our typhoid strain 706	Lister Institute "H"	1:20,480 (flocculent) (titer not determined)
Lister Institute "O"	Our typhoid 703	1:320 (granular)
Lister Institute "O" prepared by us	Lister Institute "O" prepared by us	1:5,120 (granular)
Lister Institute "H"	Our typhoid 703	1:640 (flocculent)

23. 1:80	—	? No data available		
24. 1:80	—	— Not considered typhoid		

the "O" antigen of Felix we carried out 419 tests following in all details the methods outlined above. In 307 instances the results were negative with both antigens, and in 70 instances both antigens gave a positive result. Our antigen picked up 24 positives which

were negative with the "O" antigen, but in 21 cases the "O" antigen gave a positive result when the "H" antigen was negative. As they stand these results have no relationship to the clinical situation however and it is, of course, impossible to state whether all of these positives represent actual cases. This brings up another question, namely, the value of these antigens in differentiating between the agglutinins of infection and those of inoculation. This we will consider briefly later.

Tables III and IV give the results of our efforts to determine the relationship between our results and the clinical condition, and present the actual titers obtained in those instances where positive agglutination was obtained.

It has been claimed by Felix that inoculation with heat-killed vaccines produces agglutinins of the "H" type while an attack of the disease results in

TABLE IV

SERUMS POSITIVE WITH BOTH ANTIGENS

59 serums had practically the same titer with both antigens.

11 serums varied as follows:

Our Antigen	"O" Antigen	Remarks
1. 1:80	1:200	+
2. 1:80	1:640	+
3. 1:2,560	1:160	+
4. 1:320	1:80	+
5. 1:5,120	1:320	+
6. 1:2,560	1:640	+
7. 1:160	1:640	?
8. 1:160	1:40	?
9. 1:40	1:160	—
10. 1:640	1:80	—
11. 1:80	1:80	—

the production of "O" agglutinins. Hence, it is argued that the presence of "O" agglutinins indicates infection in the individual concerned. Of course it is obvious that this would hold only if vaccines were prepared from cultures having a preponderance of "H" antigen, and it is further obvious that quantitative differences in the two agglutinins would result according to the vaccine in use at a particular time. We tested 22 serums from individuals previously vaccinated, using both antigens, and the results appear in Table V.

A casual study of this table reveals the relative accuracy of the claims of Felix. Although residual "O" agglutinins were present in some instances, they are present in quantity only after infection.

In connection with studies on the use of bacteriophage lysates as antigens for typhoid prophylaxis one of us (L) immunized numerous individuals with

bacteriophage. Although at the time this work was done a pure "O" antigen was not available, the small flaking type of agglutinin seemed to predominate. In the two instances shown in Table V the proportion of "O" antigen in bacteriophage immunized individuals was proportionately large. To be sure, these people later received vaccine, yet inasmuch as in no case did we find "O" agglutinins to such a high titer following vaccination, it would appear the result was caused by bacteriophage inoculation.

SUMMARY AND CONCLUSIONS

It is not our intention to make recommendations as a result of these studies. They are as yet too fragmentary and too limited. They do, however, verify the results reported from England and seem to us to indicate not only the desirability but the necessity for a recognition of these factors in the Widal test as done in this country. We have,

TABLE V
INOCULATED INDIVIDUALS—COMPARISON OF TITERS

A MODIFIED A. P. H. A. MILK DILUTION PIPETTE

PAUL S. PRICKETT, PH. D., AND NORMAN J. MILLER

Bacteriological Laboratories, Mead Johnson & Co., Evansville, Ind.

IN recent years a pipette calibrated to deliver both 1 c.c. and 0.1 c.c. has come into widespread use, especially in laboratories where many milk samples are plated. This 1.1 c.c. pipette, suggested by Dr. S. H. Ayers, U. S. Department of Agriculture, is recommended in *Standard Methods of Milk Analysis*¹ of the American Public Health Association. Probably this is why several laboratory supply house catalogs list it as the "A. P. H. A. Milk Dilution Pipette," although this style of pipette is commonly used in plating products other than milk.

Standard Methods cites the advantages of the 1.1 c.c. pipette for preparing two dilutions from the same water blank, for example, seeding the 1:100 and 1:1,000 plates from the 99 c.c. blank. Many laboratories prepare duplicate plates of the same dilution for incubation at the same temperature. Other laboratories likewise prepare duplicate plates, but incubate one set of plates at one temperature and the other set at another temperature. At any rate, with many laboratories making routine tests for thermophiles in milk and other products, the number of plates poured has been increased; consequently, a means of shortening the time of seeding plates without sacrificing accuracy or increasing the chance of contamination appears desirable.

These factors led one of us (P. S. P.) to design a pipette based on the 1.1 c.c. pipette, that enables the analyst to seed duplicate plates of two different dilutions from one filling of the pipette. This new pipette (see Figure 1) is calibrated to deliver 2.2 c.c. as follows: two portions of 0.1 c.c. each and two portions of 1 c.c. each.

Experimental lots of these pipettes were secured through the coöperation of a laboratory supply house.* The specifications of the 2.2 c.c. pipette follow closely the recommendations made by the committee of dairy bacteriologists that met in Geneva, N. Y., in 1926. Note that the bore is only slightly constricted at the tip; that the tip is blunt to prevent breakage; that the calibrations extend completely around the pipette; and that the distance between the 2.2 c.c. mark and the end of the pipette is sufficient for ease in handling and in filling the pipette without getting the liquid into the user's mouth.

FIGURE 1

* Will Corporation, Rochester, N. Y.

Calibration of these pipettes, by measuring mercury into them and also by weighing the amounts of milk which they deliver, showed that their variations came within the tolerances allowed for the standard 1.1 c.c. pipette.

These 2.2 c.c. pipettes were compared with the 1.1 c.c. pipettes by plating numerous samples of powdered and fluid milks whose plate counts ranged from a few hundred to several million per unit. Using the counts obtained with the 1.1 c.c. pipettes as a standard, the average per cent variation in counts obtained with the 2.2 c.c. pipettes was 5.2 per cent. The counts were based on duplicate plates of each dilution prepared; furthermore, the ratios between the numbers of colonies developing on the plates seeded with the 2.2 c.c. pipettes from different dilutions prepared from the same water blank were in proper proportion, i.e., approximately 10:1.

The saving of time is an important factor in favor of the modified pipettes. Using both standard 1.1 c.c. pipettes and the 2.2 c.c. pipettes, the average amount of time required to prepare consecutive dilutions from 1:100 through 1:1,000,000 and to inoculate duplicate plates from each of these dilutions was determined. It was found that the average time required when using the standard 1.1 c.c. pipettes was 12.4 per cent longer per dilution than when the 2.2 c.c. pipettes were used.

We are not unaware of the fact that

this pipette may be criticised because of its increased number of calibrations, for the larger the number of calibrations on a pipette, the less simple it is to manipulate. Furthermore, the smaller the volume that is measured, the larger is the per cent of error of the inaccuracies in measuring. However, these pipettes in the hands of laboratory technicians have given results that are as accurate as those obtained with the 1.1 c.c. pipettes recommended in *Standard Methods*. Another factor in their favor is that they are used only once for preparing duplicate plates of two different dilutions and are then washed.

Albus² has discussed the inaccuracies introduced in plate counts when the same pipette is used more than once. He found this factor to apply particularly to milk, especially in the lower dilutions. The fact that only one filling of the 2.2 c.c. pipette is required to inoculate the same number of plates as two fillings of the 1.1 c.c. pipette also lessens the possibility of outside contamination. Finally, with these 2.2 c.c. pipettes, a small but a distinct saving in time is made, a factor important not only in itself, but also in securing greater accuracy in the enumeration of bacteria by the plate-count method, since the interval of time between seeding and pouring the plates is decreased.

VITAL STATISTICS

The Health Record for Delaware, 1930—The significance of the death returns for the State of Delaware cannot be appreciated without consideration for the unusual composition of the population of this state. According to the Census, there were in 1930 205,778 white persons and 32,602 colored, making a total of 238,380, of whom approximately 86 per cent were white and 14 per cent colored. Beside this composition factor, there is another which is important in the consideration of the deaths from various causes, i.e., a preponderance of persons of the higher age groups, influencing the death rates from certain of the degenerative diseases, which come with advancing years.

In view of these considerations, the 1930 general death rate of 13.6 per 1,000 population was a fairly favorable one, even though it was slightly higher than the 1929 rate of 13.2. The State of Delaware attained the lowest death rate from tuberculosis in its history, 50 per 100,000 for the white population and 190 for the colored, totaling 164 deaths in 1930 as compared with 194 in 1929. Grouping the 7 infectious diseases—typhoid, measles, scarlet fever, whooping cough, diphtheria, influenza, and tuberculosis—there were in 1930, 241 deaths from these causes combined, as opposed to 329 in 1929, a reduction of about 25 per cent. Typhoid and diphtheria were the only ones of these diseases to show increases, typhoid from 5 deaths in 1929 to 11 in 1930, and diphtheria from 14 in 1929 to 20 in 1930. Measles, whooping cough, and influenza showed marked decreases, measles from 6 to 2, whooping cough from 23 to 9 and influenza from 83 to 31, from 1929 to 1930.

There was a slight reduction in the

number of cancer deaths, from 244 in 1929 to 240 in 1930; of which number 217 were among the white population and 23 among the colored, the death rate from cancer being 70 per 100,000 for the colored and 106 for the white population. This extremely high rate among the white population was attributed partially to the preponderance of persons of the older age groups, which factor was considered important also in explaining the increasing death rate from diabetes, though in this case the rate for the colored population (28) exceeded that for the white (22). The infant death rate showed little improvement, the 1930 rate for the white population (71) being the same as that for 1929, and the rate for the colored population (126) being slightly lower than the 1929 rate of 133. There was an increase from 19 to 28 in the number of puerperal deaths among the white population and from 6 to 7 among the colored population.—*Delaware Health News*, 8: 14-18 (July-Aug.), 1931.

Health Conditions in England and Wales, 1930—According to the *Registrar-General's Statistical Review for England and Wales*, which has recently been published, the birth rate for 1930 remained the same (16.3 per 1,000 living population) as that for 1929, while the death and infant mortality rates reached new low levels in 1930. There were 38,908 deaths of infants under 1 year of age, giving a mortality of 60 per 1,000 live births as compared with 74 for 1929. Contrasted with this great reduction in infant mortality, there was a slight increase in puerperal mortality, which was 4.40 in 1930 as against 4.33 in 1929.

There were 455,427 deaths from all

VITAL STATISTICS

causes, giving a death rate of 11.4 in 1930 as compared with 532,492 deaths and a death rate of 13.4 in 1929. The tuberculosis death rate for 1930 was the lowest ever recorded in the country. The number of deaths from all forms of tuberculosis was 35,745 against 37,990 in 1929 and 36,623 in 1928. The death rate in 1930 was 89.8 per 100,000 population as compared with 95.9 in 1929; for pulmonary tuberculosis, the rates for 1930 and 1929 were 73.9 and 79.3 respectively. Others among the important causes of death, which showed striking reductions in death rate in 1930 as compared with 1929, were pneumonia, which dropped from 110.7 deaths per 100,000 in 1929 to 69.6; whooping cough, which dropped from 16.0 in 1929 to 5.1 in 1930; and influenza, which declined from 73.4 in 1929 to 12.6 in 1930. It is interesting to note a substantial reduction in the death rates from heart diseases (243.6 in 1929 to 226.4 in 1930); diseases of the arteries (56.6 in 1929 to 51.2 in 1930); and cerebral hemorrhage, apoplexy, etc. (63.7 to 60.7).

As contrasted with these reductions in death rates, there were increases in measles from 8.6 in 1929 to 10.5 in 1930; in cancer from 143.7 to 145.4; in suicide from 12.6 to 12.7; in chronic nephritis from 36.2 to 36.3, and in appendicitis from 7.1 to 7.4. Death rates which remained the same in 1930 as they were in 1929 were those for diabetes (14.2) and homicide (0.5).—*The Registrar-General's Statistical Review of England and Wales for the Year 1930.*

Provisional Birth, Death, and Infant Mortality Figures, U. S. Birth Registration Area, 1930—The Department of Commerce, through the Bureau of the Census, Division of Vital Statistics, recently reported provisional figures for the births, deaths and infant mortality in the U. S. Registration Area

(exclusive of Utah) for 1930. This area in 1930 included all of the United States except South Dakota and Texas, or 94.7 per cent of the total population in the United States. Figures for Utah were omitted because transcripts for 1930 had not yet been received from that state.

According to this report, the birth rate for 1930 was 18.9 per 1,000 population, the same as the rate for 1929. In 26 states birth rates were higher in 1930 than in 1929; in 12 states the rates were lower; and in 7 they remained the same. The highest birth rate (28.5) was for New Mexico. This state also attained the highest birth rate in 1929. The greatest increases in rates over 1929 were 1.9, 1.4, and 1.3 for Arkansas, New Mexico, and Arizona, respectively. The lowest birth rate (14.1) was for Oregon, which state also had the lowest rate in 1929.

The birth registration area (exclusive of Utah) had a death rate in 1930 of 11.3 per 1,000 population. This is 0.6 lower than the corresponding rate for 1929. When compared with 1929, 37 states had lower rates in the later year, 6 had higher rates, while the rate for 2 states did not change. The highest death rate (15.5) was for New Mexico and the lowest (7.9) was for North Dakota.

The infant mortality rate of 64.2 per 1,000 live births for 1930 was the lowest rate since the establishment of the birth registration area in 1915. Thirty-seven states had lower infant mortality rates in 1930 than in 1929. The greatest decreases were 17.1 and 10.2 for Arizona and Rhode Island, respectively. The highest rates were 144.9 for New Mexico and 116.2 for Arizona. The lowest rates were 48.4 for Washington, 49.2 for Nebraska, and 50 for Oregon.

From statistics of infant mortality for 86 cities having 100,000 or more inhabitants in 1930, only 21 of these cities showed higher rates in 1930 than in

1929. The highest rates were 108.8 for Chattanooga, 102.9 for Nashville, and 101.2 for Memphis. The lowest were 37.1 for Seattle and 39.8 for San Francisco.—*Pub. Health Rep.*, 46: 2373-2374 (Oct. 2), 1931.

Principal Causes of Death in Massachusetts in 1930—There was a decrease in the general mortality of Massachusetts in 1930 as compared with 1929, the deaths in 1930 numbering 49,503. Based on the U. S. Census population of April 1, 1930, these deaths correspond to a death rate of 11.6 per 1,000 population, which is the same rate as that for 1927, the lowest rate ever recorded in Massachusetts; the rate in 1929 and 1928 was 11.9.

More than one-third of the 49,503 deaths reported in 1930 were caused by organic heart disease (including pericarditis), pneumonia (including broncho-pneumonia), and tuberculosis, all forms. These diseases, together with cerebral hemorrhage, cancer, Bright's disease and nephritis, external causes, malformations and the diseases of early infancy, caused 75 per cent of the deaths for the year.

Pneumonia caused 4,043 deaths in 1930, or 95.1 per 100,000 population. It was responsible for 4,906 deaths, or 112 per 100,000 population in 1929 as compared with 106.9 in 1928. The deaths from heart disease in 1930 numbered 11,353, or 22.9 per cent of all deaths, or 267.2 per 100,000 population, as compared with 11,528, or 22.1 per cent of all deaths, or 263.2 per 100,000 population in 1929. Tuberculosis in its various forms claimed 2,734 victims in 1930, of whom 2,423 died from tuberculosis of the respiratory system. Deaths due to the latter cause constituted 4.9 per cent of all deaths during the year, as compared with 8.1 per cent for the 5 years from 1912 to 1916. In 1910, the death rate from pulmonary tuberculosis was 133.2 as contrasted with

57 in 1930. Cerebral hemorrhage was the cause of 4,108 deaths, or 96.7 per 100,000 population.

Cancer and other malignant tumors caused 5,813 deaths in 1930, corresponding to a death rate of 136.8 as compared with 129.5 in 1929. Of the deaths from cancer 28.4 per cent resulted from cancers of the stomach and liver. The death rate from cancer has risen from 89.9 in 1910 to 136.8 in 1930. The increase has been continuous. It is possible that at least a part of this increase is due to more correct diagnosis and greater care on the part of the physicians in making reports, but a part at least is due to the lengthened span of life, resulting in a larger number of people reaching the older age groups. Diabetes was the cause of 1,021 deaths in 1930, being responsible for a rate of 24.0 per 100,000 population. The rate from this disease has shown a steady increase for the last 5 years, being 22.8 for 1929, 21.5 for 1928, and 19.8 for 1926 and 1927. Bright's disease and nephritis were the causes of 3,617 deaths in 1930, corresponding to a rate of 85.1 per 100,000 population, as compared with 79 in 1929. There were 3,485 deaths caused by Bright's disease, and 132 by acute nephritis.

Congenital debility and malformations caused 1,929 deaths in 1930, corresponding to a rate of 45.4 per 100,000 population. Diarrhea and enteritis caused 572 deaths in 1930, or 13.5 per 100,000 population. For the last 10 years this rate has shown a marked decline. Of the total number of deaths, 71.7 per cent charged to diarrhea and enteritis in 1930 were of infants under 2 years of age. The rates from this cause for all ages have declined steadily, being 21.8 in 1926, 17 in 1927, 15 in 1928, and 12.6 in 1929. Diphtheria and croup deaths numbered 182, or 4.3 per 100,000 population in 1930. Typhoid fever has shown a steady decline since

1910, having dropped from 12.2 in that year to 0.9 in 1930. This decline is greater, relatively, than that shown for any other important cause of death.

Alcoholism caused 214 deaths in 1930, a decrease of 67 from those in 1929 and corresponding to a rate of 5 per 100,000 population. Influenza was responsible for 270 deaths, or 6.3 per 100,000 inhabitants, as compared with 352.7 in 1918, 17 in 1926, and 27 in 1929.

The principal epidemic maladies of childhood (whooping cough, measles and scarlet fever) were together responsible for 417 deaths of both adults and children, or 9.8 per 100,000 population in 1930, the rates for the three diseases separately being 4.3, 3.2, and 2.3 respectively. Death rates from violence during the past 5 years per 100,000 population were 79.3 in 1926, 79 in 1927, 82.5 in 1928, 81.8 in 1929 and 82.3 in 1930. Automobile accidents and injuries caused 799 deaths in 1930, or 18.8 per 100,000 population, which is a slight increase over the last few years.—*Annual Report on the Vital Statistics of Massachusetts, 1930.*

Births and Deaths in South Australia—In many respects the latest returns from the State of South Australia show vital indices with which western Europe is familiar. A birth rate declining more rapidly than the death rate, a corresponding decline in the rate of natural increase of population, and considerable reduction in the mortality from

tuberculosis, but an increased loss from cancer. Both the birth rate (17.2 per 1,000) and the crude death rate (8.4 per 1,000) were in 1930 the lowest in the records of the state.

For many years South Australia, in common with the other states of the Commonwealth and New Zealand, has had a very low mortality rate for infants under 1 year of age, compared with other countries. In 1930 it was as low as 48 per 1,000 live births. The annual mean death rate of infants under 1 year of age for the 5 years 1895–1899 was 110, and for the 5 years 1925–1929 only 47—a fall of 63. Most of this improvement is shown to have taken place at ages above 1 month and under 12 months.

The death rates under 1 month, under 1 week, and under 1 day of age show very little progress and the great majority of those dying under 1 month of age died from prenatal causes. These facts indicate the direction in which efforts for the saving of infant life should be directed. The Mothers' and Babies' Health Association, of which there are 44 branches in the state, is endeavoring to improve the position.

Over half the population are resident in the "metropolis," defined as an area approximately within a 10-mile radius of the General Post Office, Adelaide, and roughly equal proportions of the working population are employed in agricultural and industrial occupations.—*Lancet*, 2: 415, 1931; *Canad. M. A. J.*, 25: 506 (Oct.), 1931.

PUBLIC HEALTH ENGINEERING

CONTAMINATION OF MAINS BY JUTE PACKING

CHARLES H. SPAULDING

Chemist and Superintendent Water Purification, Springfield, Ill.

THE practice of sterilizing new mains after laying and before placing in service is recognition of the fact that water has been found below bacteriological standards when drawn from new pipe. Brush¹ states that in New York City it has been the practice for many years to place chloride of lime in new mains, but the discussion of his paper and that of Absher² brings out that few of even the largest cities of the United States were sterilizing new mains in 1925. The adoption of this measure of safety in many places shows progress during the past 5 years, but even now the practice has not become general. For example, Kehr³ states that in Kansas, which we regard as a progressive state in sanitary affairs, mains are simply flushed after laying.

Kehr brings up a point which is particularly pertinent to the present discussion, namely, the *persistence* of contamination in unsterilized mains, lasting from 3 to 12 months and averaging 6½ months in 9 cases. The same picture is presented by Olson and Wright⁴ in a case where a whole year elapsed before a count of 3,000 *B. coli* per 100 ml. subsided to 1 per 100 ml.

The significance of the bacterial counts in these cases was unknown and likely to be questioned. In discussing Absher's paper, Catlett, while obviously favoring sterilization, incidentally dis-

counts the significance of the *B. coli* findings in new mains for reasons not given. Kehr mentions no cases of sickness resulting from unsterilized mains; nor do Olson and Wright. Sullivan⁵ finds 1 instance in which a state board of health attributed to unsterilized mains several cases of typhoid which could not be allocated elsewhere. One can understand that the evidence would likely be tenuous in such cases. On the other hand, the sanitary survey generally indicates the need of sterilization. Mains often lie near sewers. Frequently sewers must be broken in running a main. There are many known hazards and others unknown. Certainly, to sterilize the main before placing in service is a step in the right direction. However, if we eliminate the sources of contamination, the job may be easier.

There is ample evidence that the coliaerogenes group has been found so profusely under apparently innocent circumstances that it has been somewhat discredited as an index of pollution in those circumstances. Gerstein⁶ describes errors in sampling water from Chicago tunnels due to *B. coli* on leather packing, and mentions similar experiences related by Houston.⁷ Greer and Kells⁸ grew *B. coli* in enormous quantities on leather washers submerged in water. I have⁹ found *B. aerogenes* growing abundantly on pump packing; and Mellen¹⁰ has had similar experience. Mallman¹¹ reports *B. coli* from small pressure water systems of unquestioned safety; and more recently

* Presented before the Public Health Engineering Section of the A. P. H. A. at the Sixtieth Annual Meeting at Montreal, Canada, September 17, 1931.

the Illinois State Department of Public Health has eliminated *B. coli* from a well supply by inserting layers of HTH between the packing rings in the gland of the pump.¹²

The 1929 report of the Committee on Water Supply of the A. P. H. A.¹³ is devoted to aftergrowths of bacteria including *B. coli* in mains, showing the influence of organic matter, particularly algae, from open reservoirs. Baylis¹⁴ has demonstrated the growth of *B. coli* on dead plankton. Thus we see that *B. coli*, though admittedly the best criterion we have, cannot be accepted blindly as indication of serious pollution; and it becomes highly desirable to know their origin when present.

The writer has had considerable experience with aftergrowths of coli-aerogenes following the installation of new mains, the mains having been heavily chlorinated in each case. In some cases the bacteria found belonged to the *B. aerogenes* classification and their importance was discounted, as seems justified by present knowledge. In other cases, typical *B. coli* has been found in concentrations of 100 to 1,000 per 100 ml.; and it has been necessary to flush and chlorinate repeatedly in attempts, which were not always successful, to eliminate the offending organisms. One might expect a satisfactory sample from a main which appeared physically clean when laid; which had been plugged whenever work was interrupted, as at night; which was thoroughly flushed and then treated with chlorine in such concentration that 180 p.p.m. remained after standing 48 hours. Yet immediately following such a treatment, *B. coli* has been found in 0.1 ml. as soon as the chlorine was removed by flushing. Such behavior suggests a source of the organisms which the chlorine cannot reach effectively.

Such a source may be the common jute packing which is perhaps universally used to yarn the joints of cast iron pipe lines before the lead or joint compound

is poured. For those who are not familiar with this operation, it may be described briefly as follows:

The small or spigot end of a length of pipe is placed in the bell end of the adjoining length. This leaves an annular space formed by the bell around the spigot, which space is to be filled with melted lead. A ring of jute yarn is pushed or driven into the back of this space to close the crack between the pipes and prevent the molten lead from flowing into the main before it solidifies. A gate is then placed in front of the opening and the metal is poured. The yarn remains in the system in a position which is very difficult to reach with a disinfectant, since the only communication with the main stream of water is a narrow crack between the two lengths of pipe. Furthermore, it is capable of absorbing extremely high concentrations of chlorine, so that the small amount of chlorinated water penetrating this space is entirely inadequate to sterilize even when the concentration of chlorine is high.

There are various grades of jute packing. It is customary in ordering to specify tarred, untarred, or unoiled. The tarred jute is said by one manufacturer to be little used for water pipe on account of the odor. So-called untarred jute is lubricated with oil and is used extensively, as is also the unoiled, which is the dry fiber. Special grades of unoiled jute are available under various trade names or brands.

A considerable number of samples of jute submitted by jobbers and factories have been examined, as well as several department stocks. The method of examination is simple. One-tenth gm. of the fiber is taken aseptically from an inner strand of the twist and placed in a flask containing 100 ml. of sterile, distilled water. This is allowed to stand over night at laboratory temperature, after which a series of dilutions is planted in lactose broth, or in some cases Noble's pour plate medium has been used. Usual confirmation methods are employed. The results of examination of the first fifteen samples are shown in Table I. There are two tarred sam-

TABLE I
SHOWING CULTURES PRODUCED BY 0.1 GRAM SAMPLES

Number	Description	Coli-Aerogenes per Flask after 24 Hours	Coli-Aerogenes per lb. Jute
1	Unoil	1,000	4,500,000
2	Untarred	0	0
3	Braided (Dry)	0	0
4	Untarred	10,000	45,000,000
5	"American Hemp"	Innumerable	—
6	"Italian Hemp"	5,400	24,000,000
7	Unoil	21,000	95,000,000
8	Tarred	0	0
9	Untarred	63,000	285,000,000
10	Unoil	16,000	72,000,000
11	Unoil	50	226,000
12	Tarred	0	0
13	Untarred	10	45,000
14	Braided (Dry)	0	0
15	Special (Dry)	0	0

ples, both of which were sterile. There are four other sterile samples, three of which are grades sold at a premium and probably not generally used. The remaining nine show coli-aerogenes group in the flasks ranging from 10 to 63,000.

Assuming jute in the mains will produce at the same rate, the number per lb. will range from 45,000 to 285,000,000. If the flasks are examined after 48 hours or longer, the numbers have increased 5 to 10 times, or even more. This group of contaminated samples is believed to represent jute which is widely used for water mains as it includes samples which were first submitted. One manufacturer has recently sent in a sample which was sterile and had probably been sterilized by steam. It is possible that some sterilized jute is now being sold.

In order to simulate conditions in a main, jars were made of short bell fittings into which plugs were leaded, using portions of the packing under examination to hold the lead. The plug then formed the bottom of the jar with the packing exposed to the water as in

a main. No pressure was available to force the water through the small crack into intimate contact with the jute, and, therefore, in making the joint, the plug was kept from seating snugly by inserting a wire across the pipe, thus leaving the jute more exposed to compensate for lack of pressure. Sterile water placed in these jars made up with the sterile grades of packing remained sterile. When the other grades were used, various concentrations of *B. coli* were obtained.

Samples of contaminated jute used in making the joints were exposed over night to water which contained 9 p.p.m. residual chlorine. The result was sterile water on the following day, but upon replacing the highly chlorinated water with sterile tap water, abundant contamination appeared in 24 hours. One example is sufficient for illustration, viz., the jar chlorinated for 24 hours and refilled with tap water contained no *B. coli* immediately after refilling; but in 24 hours it was positive for *B. coli* in 0.1 ml.; and in 48 hours it was positive in 0.01 ml.

The significance of this contamination

is next to be considered. The fact that nearly all jute comes from India is not reassuring to an occidental. The fiber is derived from the bark of two closely related plants, *Corchorus capsularis* and *C. olitorius*, which have been cultivated in India for several centuries at least, and which form the basis of an important textile industry. They grow 5 to 8 ft. high, and when the crop is ripe they are cut and tied in convenient bundles. The following excerpt is taken from the 1929 edition of *Encyclopedia Americana*:

Extraction of fiber is accomplished by steeping the bundles in stagnant water, covering them with jungle plants, clods of earth or cow dung. When the setting is complete, the ryots go into the water waist deep and by threshing the surface of the water with the stalks, assisting the loosening of the bark with the fingers, the fiber is separated from the wood.

In justice of India it may be pointed out that samples of American and Italian hemp, so labeled, did not make a better showing.

From the results cited, not all jute would seem to have been treated in the unsanitary manner described by the *Americana*, because a few samples were clean in appearance and likewise sterile. The sterile brands, as before stated, sell at a premium, the price being almost twice that of the common grade. On the other hand, it has been found to cost less per joint of pipe because it is smoother, stronger and goes further. Jute packing can of course be sterilized by steam.

Using sterile jute, however, does not necessarily dispose of aftergrowths of coli-aerogenes in new mains. Opportunities for contamination are plentiful in this environment. The first rush of water carries the dust of the pipe into the crack containing the jute, and the trouble may be thus started. It is probable that the practice of dumping copious quantities of chloride of lime or perhaps permanganate of potash at the

joint is the most effective means of preventing this initial contamination. In any event, the jute yarn is likely to act as a nuisance.

From these observations we may conclude that

1. Jute is a source of contamination in new mains
2. Sanitary and unsanitary lots are on the market.
3. Chlorination of a main is an unsatisfactory method of sterilizing jute packing.
4. Jute should be shown to be free from the coli-aerogenes group before being used for water pipe packing.

Unemployment Relief—With the approach of winter the matter of providing gainful work for the nation's unemployed becomes more and more impressing. Municipalities and state governments are striving to provide funds to carry on constructive programs that will provide necessary municipal facilities and relieve unemployment. With municipal credit capable of extending construction costs over a period of years, there is every reason that it should be employed to alleviate the present situation.

New York City started work on a

\$300,000,000 project to dispose of its sewage properly. Los Angeles voted \$200,000,000 for an additional water supply from the Colorado River. Smaller cities have felt the influence of the taxpayers' leagues, bond markets, etc.; yet there is a vast amount of urgent work to protect the public health that should be done. The adequate disposal of sewage is a problem confronting thousands of American cities. The need for more extensive water supply and treatment plants was felt by hundreds of communities during the recent drought. The need of mosquito control in and about hundreds of communities in the South and along our seacoast is apparent if malaria fever is to be eliminated and workmen allowed to work undisturbed by hordes of mosquitoes. The need for adequate human waste disposal in unsewered areas is present in thousands of American towns. Clean Up Programs, that is, removal of unsightly tin cans, debris from vacant lots, clean up of city trash dumps or building of satisfactory reduction plants, the rat proofing of our water front structures, the provision of adequate play areas for the children, the creation of parks and picnic places; the demolition of structures condemned for human habitation, and the removal of the so-

called slum area from our American cities—all these directly or indirectly affect public health.

Health departments should be actively interested in unemployment relief, and now is the time to get the sanitation projects under way. Labor is cheap, material is cheap, and the unemployed need work. Clean up the sewage disposal plant, put it in operating order or build a new one. Develop that additional water supply and new purification plant. Fix up the sanitation about the city limits. Get rid of malaria and dengue fevers, and do the drainage or cleaning up work to prevent mosquito breeding. Health departments shall lead the way. Public health can best be protected by having work on health protecting projects carried on.

Your A. P. H. A. Committee on Economic Aspects of Public Health Engineering Projects urges health officers to present forcibly the benefits to their communities of such engineering projects that will combine public health protection and unemployment relief.

FOOD AND NUTRITION

Vitamin Content of Turnip Greens, Collards, Cantaloupes and Peaches—The methods used for determining the vitamin A, B, and C content of turnip greens, collards, cantaloupes and peaches were based on the Sherman technic. Studies were made on the turnip greens raw, boiled and canned. One oz. of raw turnip greens contained 1,418 units of vitamin A, approximately 14 of vitamin B and 95 of vitamin C. Greens boiled 45 minutes contained an equal amount of vitamin A but only 14 units per oz. of vitamin C. Greens boiled 2 hours contained 6 units per oz. of vitamin C. Canned greens which had been blanched in boiling water contained 7 units per oz. of vitamin C, while the steam blanched canned product contained 14 per oz.

Raw collards were found to contain 1,418 units of vitamin A per oz., about 28 of vitamin B, 28 of vitamin G, and 57 of vitamin C. Collards boiled 2 hours had lost no appreciable amounts of their vitamin A, B, or G content, but contained only 14 units of C per oz.

Fresh yellow cantaloupe was found to contain 95 units of vitamin A per oz., about 7 of vitamin B per oz., and 10 of vitamin C per oz.

Frozen Elberta peaches were found to contain approximately 14 units of vitamin A, and less than 0.5 of vitamin C per oz. The frozen Hiley variety of peach contained less than 14 units of vitamin A and less than 0.5 unit of vitamin C per oz.—Catherine L. Newton, Georgia Exper. Sta., *Bull.* 167 (Aug.), 1931.

Vitamins in Canned Foods—XI. A Canned Food Diet—The experiments here reported were directed primarily to a study of the stability of the

vitamins to the canning process. Tests for vitamins A, B and C were made. The canned foods were purchased at grocery stores and represent those available to everyone. The foods were not irradiated nor did the animals receive irradiation or direct rays of the sun.

Three pairs of young guinea pigs, weighing 320 to 430 gm., and one pair 3 weeks of age, and 3 pairs of young rats, 23 days of age weighing 53 to 56 gm., were placed on a diet consisting entirely of canned foods sterilized by heat. When this report was made, the experiment with rats had been in progress for 15 months and that with guinea pigs for 12 months. During this time, the rats had reached the 5th generation and the guinea pigs the 3d.

Each generation was thriving as well as under any conditions. Reproduction was as prolific as could be expected, the size of the litters normal, in every way, and lactation was adequate. The rate of growth and weight at maturity was much higher than that reported as normal. The evidence indicates that canned foods may supply every dietary requirement, including vitamins B (B_1) and C, so often referred to as heat labile.—E. F. Kohman, W. H. Eddy, and Celia Zall Gurin, *J. Indust. & Eng. Chem.*, 23: 1064 (Sept.), 1931.

Salmon Oil and Canned Salmon as Sources of Vitamins A and D—In this experiment, albino rats weighing 40 to 45 gm. were placed upon a vitamin A-deficient ration, as follows: alcohol extracted casein, salt mixture IV, agar, yeast, dextrinized corn starch and peanut oil. When distinct symptoms of ophthalmia occurred, the curative tests were begun. The salmon oils used were humpback, sockeye, chum, chinook, and

silver. Curves are given showing the different results obtained. It is apparent that the oils vary widely in their vitamin A potency and there was a striking correlation between depth of color and vitamin potency. The oils which showed a distinct reddish cast, as chinook and sockeye, contained more vitamin than chum which had practically no red color. Oils from the offal of salmon of the 5 species were found to be excellent sources of vitamin D. Three of such oils, humpback, sockeye, and chinook, were fully twice as potent as a medicinal cod liver oil, chum oil about 50 per cent more potent, and silver oil about equal to cod liver oil in vitamin D.—C. D. Tolle and E. M. Nelson, *J. Indust. & Eng. Chem.*, 23: 1066 (Sept.), 1931.

Vitamin A Content of Body Oils of Pacific Coast Salmon—These were made to secure quantitative data upon the relative vitamin A content of body oils of 5 common species of Pacific Coast salmon widely used as food. The common names of the 5 species are Chinook, Sockeye, Silver, Humpback, and Chum. The vitamin A content of the body oils was determined by the biological assay recommended by Sherman and Munsell and for comparison a medicinal cod liver oil was used as a control.

Young albino rats, 28 to 29 days old, weighing 35 to 55 gm., were placed on a vitamin A-free diet, otherwise adequate. When their bodily store of vitamin A had been depleted, they were replaced in individual cages and their diet was supplemented by the oils being tested.

Each animal received daily 93 mg. of chinook oil, 186 mg. of sockeye oil, 226 mg. of silver oil, 227 mg. of humpback oil, 221 mg. of chum oil, and 1 mg. of cod liver oil. All the salmon body oils tested were found to be decidedly inferior to a medicinal cod liver oil of high grade as a source of vitamin A.

Chinook and sockeye oils were found to contain more vitamin A than the other three oils tested.

Two hundred and twenty-seven mg. of humpback oil barely maintained life over the 8 weeks, and 221 mg. of chum oil failed in all cases but one to do so, the animals dying within from 5 to 7 weeks. It is noted that the vitamin A content of these oils falls in the same order as fat content of the flesh as determined by Shostrom, Clough, and Clark (*Ing. Eng. Chem.*, 16: 283, 1924), and, with the exception of the chinook, the reddest fish were also the richest in this vitamin.—R. W. Truesdail and L. C. Boynton, *J. Indust. Eng. Chem.*, 23: 1136 (Oct.), 1931.

Chemical Changes in the Fat of Frozen and Chilled Meat. I. Frozen Mutton and Lamb—In the experiments here reported, changes in the chemical composition, appearance and flavor of the fat of carcasses of lamb were observed during precooling, cold storage at -5° , -10° , and -20° for periods up to 7 months and during hanging at room temperature subsequent to storage.

A temperature of -5° failed to prevent the growth of molds and yeasts on the carcasses. No visible growth occurred at -10° or -20° , and the fat of the meat stored at the 3 temperatures did not seem to be attacked by microorganisms when held for 3 days at a mean temperature of 12° subsequent to storage.

The free acidity values recorded were of the order of 1.2 per cent (as oleic acid) for external fat and much less for kidney fat.

II. Chilled Beef—In the case of chilled beef, oxidation of the fat was not sufficient to render it unpalatable, provided undue exposure to strong light was avoided. Portions of the fat, particularly the front edge of the breast were, however, found to acquire, on

prolonged storage, a tainted flavor. Measures, such as the use of air circulation, or of a storage temperature of -1.6° in place of 0° , which produced conditions less favorable to the growth of microorganisms were found to extend the storage life of the fat and hence of the meat.—C. H. Lea (*J. S. C. I.*, 1931, 50: 207-213 t, 215-220 t). Abstract *J. S. C. I.*, 50: 779 (Aug. 21), 1931.

Chemical Changes in the Fat of Frozen and Chilled Fat. III. Frozen Bacon—The experiments were undertaken to discover the cause of the deterioration in the fat during storage and to obtain information on the keeping qualities of the fat of (1) smoking, (2) variations in composition of the feed including the addition of cod liver oil in small quantities to the diet, and (3) immediate cooling of the pork at 5° C. (40° F.) after dressing instead of at ordinary temperature.

The free acidity values observed in the fat of tank-cured bacon during storage at -10° for periods up to 152 days followed by hanging at 15° for 18 days gave no indication of attack by microorganisms on the fat, nor were any signs

of tainted flavor observed. The superficial fat of freshly cured bacon was found to contain small quantities of active oxygen which rendered the fat very susceptible to further oxidation during storage.

When stored at a temperature of -10° the exposed surface of the fat oxidized rapidly, but without developing any appreciable yellow color in 152 days. At 15° the bacon was found to become yellow on the surface and, after cold storage, sometimes in the interior of the fat. On cooking the oxidized portions of the fat had a rancid flavor. Smoking considerably improved the resistance of the bacon to attack by microorganisms, the surface of the bacon being practically free from mold, while the controls were badly contaminated with white and green molds and yeasts.

Rapid cooling at 5° prior to curing seemed to have no appreciable effect on the fat. The addition of cod liver oil to the diet, even in small quantities, appeared to have a harmful effect on the keeping qualities of the bacon, although no effect on the iodine value of the fat. —Colin H. Lea, *J. S. C. I.*, 50: 343 t (Sept. 11), 1931.

INDUSTRIAL HYGIENE

Industrial Hygiene in New York State—The New York State compensation law schedules 27 occupational diseases and poisons of which only 18 were mentioned in applications in 1930. While it is possible to prove that the compensation act has resulted in a positive economy to the manufacturer, proof is not at hand to show that prevention of occupational diseases has been of monetary benefit to him.

The Division of Industrial Hygiene had its origin in the recommendations of the New York State Factory Investigation Commission of 1912. Thus the primary object of the division today is the prevention of industrial accidents and occupational diseases. The background of the efforts may be stated in a few words:

The population of New York State, on April 1, 1930, was 12,588,066, of which number about 3,000,000 came within the operation of the workmen's compensation act. New York, like other states, has a small number of large plants and a large number of small plants; e.g., there are hardly 400 plants in the whole state which have 500 employees or more, although there are 60,000 establishments whose output is \$5,000 or more per annum. About 92 per cent of the establishments have 50 employees or less. Also, the state has no less than 200 industrial groups, each one with a great variety of occupations. During 1930, 109,848 compensation cases were closed (at a cost amounting to \$35,243,703), of which 423 were due to occupational disease lasting for a week or more. Less than \$1,000,000 a year is provided for prevention, of which only one-tenth is spent on industrial hygiene. Even in

the large establishments, which afford medical departments, there is very little evidence of activity by plant physicians in the prevention of occupational disease.

The division's secondary functions are to assist in the operation of the workmen's compensation act, to provide information for the Industrial Board and other divisions of the Department of Labor as well as the medical profession and the public. In the matter of prevention the chief function has to do with accidents since, roughly, only 0.5 per cent of all present compensation cases are occupational diseases.

The staff of the division comprises 24 persons, including medical inspectors, chemists, safety inspectors, engineers, plan examiners, investigators, safety lecturers and demonstrators, and clerical help.

The medical inspectors visit industrial plants to determine the cause of occupational diseases and to ascertain whether conditions are inimical to health as well as to determine specific hazards such as lead, carbon monoxide, or chromium. The chemists secure samples of materials alleged to be dangerous and analyze them, and likewise make determinations of atmospheric conditions. The engineers examine plans and ventilating systems in accordance with the industrial codes. During 1930, 683 ventilation plans were submitted for approval, of which 605 were approved and 78 disapproved. Also 6 studies or monographs on accident causes and prevention were made in addition to lectures, exhibits, demonstrations and special statistical studies.

The reporting of occupational diseases by physicians on the standard

INDUSTRIAL HYGIENE

official certificate (Form 313) is practically inoperative for several reasons such as the inclusion of only a few of the more obvious diseases on the schedule, the failure of many physicians to recognize an occupational disease, and the lack of remuneration for reporting the same as well as a penalty for failure to do so. Therefore, information regarding occupational diseases is difficult to get and the chief sources come from the compensation act and certain requests and hearings.

During 1930, 770 cases of occupational diseases were reported, the chief being: lead 350, benzol 36, chromium 29, carbon monoxide 21, dermatitis about 150. A considerable reduction of lead cases is expected as the result of the action of the principal lead battery manufacturers which have followed the recommendations made by the division; thus, whereas 254 lead cases were reported in 1930, there were only 15 during the first 6 months of 1931.

The medical staff has prepared several monographs, e.g., on lead, carbon monoxide, and chrome poisoning, and more recently a series of "industrial hygiene leaflets" to inform physicians, employers and workers about occupational poisons and diseases. It has been found a most difficult thing to popularize knowledge of occupational diseases where they occur only here and there in the vast extent of the state.

In the future, closer coöperation is to be sought with the state and municipal health authorities whose help is needed and whom we need to help. Likewise, the extension of the division is to be hoped for and expected with far more stress on prevention as well as the inclusion of all occupational diseases in the compensation act. It is highly necessary that a clinic be set up for the purpose of diagnosis, prevention, and determination of sensitivity. The extension of publicity is also desirable.—J. D. Hackett, Director, Div. Indust. Hyg.,

New York State Dept. of Labor. Abstract of paper presented before the Industrial Hygiene Section of the A. P. H. A. at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.
E. R. H.

The Eastern Interstate Conference on Labor Legislation, June 18-19, 1931—The conference, held in Harrisburg, was called by Governor Pinchot and was composed of representatives of the governors of a considerable area of eastern states for setting standards for labor legislation to meet the needs of an industrial area. The conference was made up of representatives from the states of Connecticut, Delaware, Maryland, Massachusetts, New Jersey, New York, Ohio, Pennsylvania, and West Virginia; and the U. S. Department of Labor.

The discussion was limited to the consideration of standards for workmen's compensation, for employment of women and children, industrial health, and labor statistics, and recommendations as to minimum standards. This is considered the beginning of a movement which recognizes the needs and problems of industry irrespective of state boundary lines, and a continuing body was appointed to meet again for further study of the questions involved.

Recommendations of the section on industrial health referred to the following features: ventilation, temperature, humidity, lighting, air space; drinking water; toilet facilities, wash and dressing rooms; lunchrooms; seating facilities; cleaning and physical upkeep of places of employment; first aid; general health consideration (referring especially to building construction and equipment); and occupational diseases.

Simply, "adequate standards" were recommended for ventilation, temperature, humidity, lighting, etc., and it was prescribed that specific minimums be not adopted in the law on these points but

that power be lodged in the administrative authorities of each state to establish such standards. The highest standards now found in existence in labor laws are to be considered as well as consultation with the U. S. Public Health Service, the American Public Health Association, the American Standards Association, the National Safety Council, and other similar organizations.

It was also recommended that reports of all occupational diseases shall be rendered by all physicians diagnosing and (or) treating such cases, and by all employers having knowledge of cases of such diseases among their employees. "Protective devices and measures necessary for the prevention of any or all occupational diseases shall be required."

Other sections dealt with recommendations on employment offices and on the matter of statistics. A fairly large number of prominent persons were assembled to compile the recommendations of the various sections.—Pennsylvania Dept. of Labor & Industry, *Labor & Indust.*, 18, 7: 3-17 (July), 1931.

E. R. H.

Committee Reports—Four of the various committees of the Section on Industrial Hygiene rendered reports at the Montreal Meeting as follows:

The Committee on Standard Practices for the Compensation of Occupational Diseases, of which Dr. Lanza is Chairman and for which Dr. Kessler read the report, devoted its time to the subject of Silicosis, urged on by the situation in New Jersey, the recent conference in South Africa, and the experience of Ontario; and considered the matters of administration, standards of diagnosis, time of exposure, and compensation. By order of the Section, this committee was instructed to combine with the Committee on Pneumoconiosis (below) and to render a joint report which was done at a later session of the same meeting.

The Committee on Pneumoconiosis, of which Dr. Sayers is Chairman, rendered a report to further uniformity of terminology and definitions, stages and diagnosis of silicosis, and was requested to render a combined report with the above named committee as indicated, Dr. Sayers to be Chairman of the Joint Committee.

The Committee on Industrial Fatigue, of which Dr. Eugene L. Fisk, deceased, was Chairman, presented a report by Dr. Frederick B. Flinn, Acting Chairman, which referred to the maintenance of the bibliography on this subject and several features in the study of fatigue and the committee was instructed to proceed under Dr. Flinn.

The Committee on Lead Poisoning, of which Dr. Hayhurst is Chairman, exhibited a complete bibliography for the year 1929, and distributed mimeographed copies containing brief abstracts of part of this, the work being the accomplishment pretty largely of Clareiss T. Rayne, Secretary of the Association's Committee on Research and Standards; also, a statistical statement for the year 1929 prepared by Dr. Fredetick L. Hoffman, a member of the committee. Furthermore, Dr. Joseph C. Aub, a member of the committee, presented a paper accompanied with X-ray illustrations upon "The Significance of Bone Trabeculae in the Treatment of Lead Poisoning."

The four reports of the above named committees will be printed in the Association's *Year Book*, except the extensive bibliographies in connection with some of them, which may be obtained either in part or in whole from the Association's headquarters. E. R. H.

Silicosis in the Abrasive Powder Industry—Recently, in New Jersey, over 100 cases of silicosis are alleged to have occurred in the abrasive powder industry, involving 4 companies which pumped up sand by hydraulic pressure

to a plant where it was washed, steam dried, screened into various sizes and then pulverized in closed tube mills. The free silica content of the completed product was approximately 99.24 per cent, and of the order of $1-5\ \mu$ in size. The silica powder was packed by mechanical means into large cotton bags. Dust arose at the tube mill and in packing, although apparently efficient exhaust ventilation was present; also, in handling and carting the bags. The men wore ordinary Wilson type respirators; positive pressure air-line masks having been found impractical or inefficient. Another place of hazard was bag cleaning and repairing, usually done by women. Young colored adults were employed in the main mill room.

Silica powder is used in about 20 industries, especially the glass, pottery and abrasive cleaner industries.

While most of the claimants were employed at or near the packing operation, others were in the wet processes, and several women were in the bag cleaning work. Six persons have died and have been autopsied by Dr. Martland of Newark. Many others have been reported to have died but the results of the autopsies in these cases are not known. Of 40 X-rays of cases reviewed by the author only 4 could be called ante-primary, although some others showed varying degrees of fibrosis without characteristic mottling.

The most outstanding feature of these cases has been the allegedly short exposure period—apparently as brief as 4 months to $1\frac{1}{2}$ years. Others have had an exposure as long as 6 years. Many of the cases have been seen by competent observers and studied by roentgen rays and reported as first or second stage silicosis.

In comparable experience, Irvine, of South Africa, has observed only 1 case which occurred in less than 6 months' exposure—this in a miner who was confined in a very small work space; Hay-

hurst (in Ohio) found only 1 case with 1 year or less of exposure in 919 sandstone quarry men; D. G. Robertson, of Australia, found the average period of employment in mine workers with detectable silicosis to be 21 years in surface work and 26 years in underground work; Adelaide Smith, in rock drillers and blasters in New York City, found the shortest exposure to be 3 years; Muller reported 3 years in sandblasting; Kraestle 10 years in the porcelain industry; Bohme 10 to 15 years in stone-borers. Mavrogordato reports 10 to 11 years as the mean duration of exposure before the disease is clinically recognized, while Sutherland and Bryson report 20 years in the sandstone industry before the disease is recognized. The Ontario Silicosis Scheme places a minimum of 3 years' exposure in the stone industry and 5 years in the mining industry before compensation is paid. This has been done to distinguish between fibrosis and other disease or dust exposures than silica, for the law compensates silicosis only.

The New Jersey situation therefore appears unique in the matter of the short length of exposure "or that fibrosis due to other causes is being mistakenly regarded as silicosis."

While the plants concerned have taken precautionary steps, further engineering improvements are desirable, as well as shorter hours with alternation of exposure periods, medical examinations and the addition of some chemical agent to the silica powder which will take up water from the atmosphere and keep it moist without impairing its properties.

(In the considerable discussion which followed the presentation of this paper it was brought out that preemployment examination of these workers had not been made so that the possibility of longer periods of exposure to silica was present, while both the author of the paper and the discussants felt that much more intensive work should be done on

the situation before deriving final conclusions.)—Henry H. Kessler, M.D., Newark, N. J. Abstract of a paper presented before the Industrial Hygiene Section of the A. P. H. A. at the Sixtieth Annual Meeting at Montreal, Canada, September 15, 1931.

E. R. H.

Asbestosis Bodies in the Sputum: a Study of Specimens from Fifty Workers in an Asbestos Mill—Author's summary:

The inhalation of asbestos dust in high concentrations leads to the appearance of asbestosis bodies in the sputum in a large percentage of the workers exposed thereto. They were

present in 48 out of 50 workers examined.

Asbestosis bodies were as easily demonstrated by direct thick films as by the antiformin method.

The sputum was always mucoid in character when there were no bronchial complications. It may resemble egg albumen. In none of the sputums were tubercle bacilli demonstrated.

Study of the intracellular asbestosis bodies in these cases suggests that they are formed by the deposition on the asbestos fiber of an iron-containing substance elaborated by the cell.—F. W. Simson and A. Sutherland Strachan. *J. Path. & Bact.*, 34, 1931, 4 pp.

E. R. H.

CHILD HYGIENE

HEALTH OF THE ADOLESCENT

NO one who is at all familiar with problems relating to adolescence will doubt that the health equilibrium during this period, from both the psychological and physical standpoints, is rather unstable. Growth and development during adolescence are very perplexing. The significance of this period is probably least understood of all the periods of growth, and demands concentration on special studies of many kinds.

During adolescence we cannot apply the same standards of growth and development as are used during earlier periods. It has been clearly pointed out by many investigators that in this period there is lag in both height and weight, and that this is followed by a distinct spurt in growth after the 15th year. The acceleration of growth as a factor in weight begins somewhat earlier in girls than in boys. For the most part the tables of height and weight which have been used as criterions for malnutrition should be laid aside and judgment should be based upon careful physical and mental examinations of the child, together with a survey of his health habits. There is a great need for a better construction of standards of growth and development in the adolescent child. Growth implies not only increase in height and weight, but also increase in the integration process of the organism on its way toward maturity. Within each individual there seems to be an inherent power of growth toward a goal or pattern, and this applies to the individual organs and the body as a whole.

A wider knowledge of the social and emotional experiences, in relation to growth, through which the child passes in adolescence is extremely important. It is a period of constant, and sometimes rapid, changes of the individual parts of the body, and of one or another part in relation to the whole. While a considerable amount of literature has appeared in recent years dealing with various phases of adolescence, we still are in doubt about certain of the processes of growth, and especially concerning the exact action of the endocrines. There is no question that the endocrine glands exert powerful influence upon the adolescent development of both sexes. Ample evidence is at hand, showing that development of the sex glands is closely related to the functioning of the thyroid and pituitary bodies. At this period there is intimate relation between the growth of the long bones and development of fundamental muscles. Both of these give to adolescent development its chief characteristics of increase in weight, height, and body growth. It is well known also that the muscles are intimately related to every other system in the body.

During the second decade there is a greater demand for activity on the part of the large skeletal muscles and this is manifested by the interest of the adolescent in outdoor sports requiring considerable endurance. Disproportion in growth between muscle and bones, or between two sets of muscles, may take place, resulting, as we know, in awkwardness, slovenly gait, poor posture, and asymmetrical development. This is

a period in which the growing youth needs particular attention from the standpoint of corrective exercises and skillful direction of athletic sports. The growing muscles demand oxygen and fuel, and this leads to distinct changes in the circulatory and respiratory systems. There is evidence to show that before the accelerated growth of adolescence the heart is relatively small in proportion to the large blood vessels. During adolescence the heart develops rapidly in size and in strength of beat, and its capacity enlarges. The vital capacity of the body is also increased considerably. It is a serious question whether the skeletal muscles do not grow at a greater rate than the heart during this period, thus placing an extra burden upon the latter, especially during strenuous exercises.

We know, from clinical evidence, that the heart of the adolescent boy or girl is prone to be affected by the acute communicable diseases. It is very important, therefore, to examine carefully every adolescent boy and girl returning to school after one of the infectious diseases. A number of unpleasant incidents have been reported in which the boy or girl has suffered from acute dilation of the heart when playing strenuous games, such as basketball, after having had influenza or one of the other acute infectious diseases. The question naturally arises whether the strain to which the heart is subjected during adolescence will manifest itself later in weakness and premature breakdown. On the other hand, the healthy, normal heart of adolescence makes very rapid adjustment, and compensates for the damage done in other respects.

One of the most difficult problems at present is the increase of tuberculosis among high school children. For several years there has been noted a distinct tendency for tuberculosis rates to rise among adolescent girls. This has been attributed to many factors, such as

chronic fatigue, fads in dieting, and scanty clothing during the winter months. Studies are now being conducted in a number of places which reveal the origin during adolescence of the adult type of tuberculosis. This brings forcibly to us the importance of very careful examination, supplemented with X-rays, of high school students.

Studies concerning absenteeism in secondary schools have revealed sickness as a major cause of absence. Diseases of the upper respiratory tract and gastrointestinal diseases appear to be the most important ones among high school population. The acute communicable diseases, other than common colds and influenza, do not seem to play a large part in absenteeism. It has been found that when the secondary school employs a capable nurse, who can check up on the absences and follow up cases to the home, the number of days of absence has been reduced considerably. This gives the nurse an excellent opportunity not only to conduct classes in personal hygiene in the school, but also to use the occasion of her home visits and her contacts with the teachers to enforce the lessons of hygiene and sanitation.

One of the most important disorders, occurring in the Great Lakes region and in the mountainous areas of the United States, is simple or adolescent goiter. Using the epoch-making work of Marine, Lenhart, and Kimball, we are in a position to prevent this type of goiter. The regular administration of small quantities of iodine, consistently carried out, especially to girls between 12 and 16 years of age, has decreased considerably the percentage of goiter. Medical examiners and nurses in the high schools should constantly be on the look-out for signs of this disorder. Many of the girls having it are hyper-active, very intelligent, and make high grades; they are usually thin and nervous, and have rapid heart action. Some of these cases

have been confused with tuberculosis, but the diagnosis may be made readily by means of thorough physical examinations, basal metabolism tests, and the use of the X-ray and tuberculin.

Provision should be made in the high schools so that girls having slight ailments and needing periods of rest may have the use of comfortable cots. The exercise of both boys and girls should be regulated carefully so as to adapt itself to the requirements of each individual child.

Problems of nutrition come to the front of this period. Bad habits of eating and poor selection of food begin to show results in lack of vitality and fatigability of the high school boy and girl. Ample provision should be made

for a lunchroom where well balanced meals, including a liberal supply of milk, are served. Definite instructions should be given regarding values of the food elements and the composition of foods. Something should be taught as to the relative cost of different foods.

This brings us to the whole problem of health education in secondary schools. There are a number of subjects with which health may be correlated in the secondary schools, but it is important, in addition, that some one individual be made responsible for bringing about this coordination and keeping in close touch with all the activities of the school which bear upon the child. This need is being met in some places by a health coordinator or correlator.

PUBLIC HEALTH NURSING

The Development of Nursing in China—Nursing as a profession has been known in China for comparatively few years. In this regard "New China" is slowly emerging from the isolation of ages. However, there are millions of Chinese who still believe in the presence and power of demons. Charlatans thrive in producing charms and amulets to combat the attacks of ills which afflict the human body which are supposed to be caused by the visitations of specters.

Chinese doctors of the old school are found everywhere. They use quaint drugs and wonderful prescriptions, and scientific training is not considered necessary for them. The same is true of the midwives; they have no special training, but what they know has been passed down from their mothers and grandmothers. They do untold harm as they do not know the rudiments of cleanliness or asepsis.

But Chinese women are now being trained as nurses and doctors due to the early activities of the Christian missionaries who realized the need of proper medical care for Chinese mothers. Twenty years ago the Nurses Association of China (N. A. C.) was formed; this gave impetus to the training of Chinese girls for nursing. In 1929 the N. A. C. sent 5 delegates, 3 of whom were Chinese, to the International Council of Nurses Quadrennial Congress held in Montreal, Canada. It was at this meeting that the N. A. C. became affiliated with the Council.

At the tenth biennial conference of the N. A. C. in 1930 the Minister of

Health of the Chinese National Government in an address said that it was estimated that there was only 1 nurse in China to about 200,000 people. The President of the N. A. C. at the same meeting said, "Properly trained nurses who are able to give instruction and advice in health matters are a necessity. The education of nurses is a public responsibility."

Now the Government of China is taking great interest in the training, registration and protection of nurses. The General Secretary of the N. A. C. has been appointed Director of Nursing Service of the Ministry of Health.—J. G. Cormack, Another Aspect; The History of Chinese Nursing. *Nurs. Times*, 1375: 971-972 (Sept. 5), 1931.

Public Health Nursing in Rural Industrial Communities—In a rural community, assembled to promote some industry, the problems of hygienic and wholesome living and the problems of sanitation are accentuated. It is fair to consider the public health work of a large concern like the Consolidation Coal Company of Pennsylvania, West Virginia, and Kentucky as an example of what should be done in all rural industrial communities to make the "bodies and minds" of their employees to "function normally."

Ten thousand employees of the Consolidation Coal Company and their families are scattered in mining communities in the 3 states named above. The territory is divided into 6 divisions, the minimum distance between any 2 being 60 miles, and the maximum 300 or more miles. Because of these scattered areas it has been necessary to establish 14 medical units with 23 phy-

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex Indianapolis, Ind

sicians, 12 staff nurses and 1 supervisor. In Elkhorn Division in southern Kentucky there is a fully equipped 50-bed hospital which has been approved as a first class hospital by the American College of Surgeons.

The few cases of communicable disease speak well for the immunization program. In all the communities the applicant is given a physical examination and if accepted he and his family receive typhoid and smallpox vaccination immediately.

The charge for medical service to the employees and their families is \$1.00 for a single man and \$1.50 for a married man, and this amount is deducted in each case from the pay roll. An extra charge is made by the physician for obstetrical and venereal disease cases.

A school health program similar to that being installed in the schools of Pennsylvania was instituted last year.

The 12 public health nurses, dressed in dark blue silk uniforms and carrying black leather bags, fitted for their varied activities, inspect school children, make home visits, conduct mothers' classes, and boys' and girls' clubs, distribute health literature, and conduct infant welfare clinics. A full-time dentist is employed for some of the schools.

A monthly sanitary inspection of camps, and milk and water supplies, is made by the sanitary squad, which includes the personnel manager of each division, the superintendent, the doctor, nurse, and a representative of the Building and Civic Improvement Department. Recommendations made by this squad are given serious consideration.

The company issues a monthly newspaper which is extensively used as a health advertising medium.

Since the time of the inauguration of this program in 1927, through a continuous process of education, the communities have learned to appreciate that when a work of this kind must be limited for economic reasons, much more

can be accomplished through a preventive than through a curative program—Hilda S. Nelson, R.N., Public Health Nursing in Rural Industrial Communities, *Trained Nurse & Hosp. Rev.*, Aug, 1931, p. 208
V A J.

A Western Experiment in Nursing Education—The education of the nurse has had to be broadened in recent years to keep pace with the advances in the field of medicine. More comprehensive courses in the laboratory sciences have called for increased laboratory equipment and facilities, which entail a greater outlay of funds than most hospitals have available for this purpose, unless they increase their revenue by raising the cost to the patient or rely on philanthropic individuals. Nurses render service to the public, and it seems only logical that the public, which pays for the education of doctors, lawyers, and practically every other professional group, should be given the chance to participate in the education of nurses.

Nursing education leaders have worked hard to interest educational institutions in affiliating with nursing schools to give pupil nurses varying amounts of instruction not only in the basic sciences but also in basic and technical and professional subjects included in a 5-year course leading to a B.S. degree.

When the Board of Education of the City of Los Angeles, Calif., opened its Junior College in 1929 the California League of Nursing Education, Southern Branch, appointed a committee to arrange an affiliation between nursing schools and the college. A pre-nursing course of study covering 1 full year at the Junior College was planned for students wishing to enter schools of nursing. During the year 1930-1931 the California Lutheran Nursing School, the Methodist Hospital Nursing School, and the Bishop Johnson College of Nursing participated in this joint arrangement.

Some advantages of the arrangement:

1. The laboratory equipment is much more complete than the ordinary nursing school could afford.

2. Subjects are taught by specialists in each particular line with years of teaching experience behind them.

3. The student nurses have contact with other college students.

4. It helps eliminate the undesirable student, as the Junior College drops the student at the end of 10 weeks if she fails to pass in 10 units.

The greatest possibilities for developing nursing education along the lines demanded by advancing medical science and practice seem to lie in schools that are independent of, but affiliated with, hospitals and colleges; that are controlled by the League of Nursing Education, and supported by State funds.—Lena E. Moede, R.N., *The Los Angeles Experiment in Nursing Education*, *Western Hosp. Rev.*, Oct., 1931, p. 16.

EDUCATION AND PUBLICITY*

Ill-Advised Advisers—A picture, "Night Nurse," recently released emphasizes a danger which crops up in unexpected places. For the argument against this picture see "Powerful Defense by the American Hospital Association" (*American Journal of Nursing*, Oct., 1931) which states that

The picture is a distinct reflection upon the hospital operation and its portrayal of the character of the nurse reaches a point where it approaches the scurrilous.

A letter from the Motion Picture Producers and Distributors of America states that

... the studio affected secured the services of an eminent physician in California and followed his advice regarding the details of hospital technic as well as the portrayal of the nurses and physicians as shown in the picture.

Not long ago a commercial food association issued a pamphlet of doubtful utility to the schools to which it is being supplied. "The pamphlet was approved by a leading educator," was the reply to a letter in which we questioned its use in schools.

Because of quirks in the judgment of individuals and the all too common lack

of analytical minds almost any proposal in health education may find its endorser among leaders in professional groups.

It is no light responsibility to advise commercial interests or health agencies as to the validity of their data and the form of presentation. It is easy to be too up to date in sponsoring ideas not finally accepted by science. It is equally possible to cling too long to discarded notions. Personal prejudices and limitations of our own experience need to be checked.

Advertisers may guard against mistakes by consulting widely before choosing advisers. And professional advisers may well seek consultation with others in the profession.

Instruct Your Representatives—Suggestions for the program and other activities of the Public Health Education Section are invited by its officers in preparation for the January meeting of the Section Council.

Awards But No Contest—All varieties of educational publicity material will be considered by the Awards Committee of the Social Work Publicity Council. Whatever the form, whatever the source, the committee will

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

evaluate it on whatever consideration it seems to call for recognition. All material sent to this department, as well as what goes to the S. W. P. C., will be in line for awards.

Borrowed Gems—Good ideas and good writing, and pictures, too, are being passed on to other audiences.

The noted borrowings in bulletins or house organs have included quotations from daily papers, *Hygeia*, city and state bulletins, general magazines, and press releases of radio talks.

Ohio, Massachusetts, New York State, Michigan, Lincoln, Detroit, Texas, Massachusetts Mental Hygiene, Oakland Health Center, and Wisconsin Anti-Tuberculosis bulletins were among those quoting from the wealth of good material which might well be passed on to additional audiences.

They Have So Much to Share—Last winter about 50 book people met a number of times fortnightly in New York City. They are meeting again at intervals this winter. All they have to discuss is the planning of the paper, typography, printing and binding of books.

Is it possible that small groups of those concerned with public health education could get together to discuss how to get people to read, to listen, to act?—and how to that end to make use of printed matter, radio, motion pictures, and the whole range of mediums available for awakening interest and spreading information?

Food Store Window Displays—Bellevue-Yorkville and East Harlem Health Centers, New York, both had grocery window display contests this fall. Awards were made on the basis of the food values of the stock displayed, as well as for its selling effectiveness.

In addition to the details of the contest plan as worked out by the two

health centers two points may well be considered when such contests are put on in other cities:

1. To provide a colorful placard or poster (amateur-made or otherwise) to tie up the window with the current food selection campaign—and to emphasize that such selected foods are sold in that store
2. To give information about—or better—to provide copies of window display suggestions to be secured free from display material manufacturers.

A brief memorandum of such material now available will be supplied by the editor of this department. Enclose an addressed and stamped envelope.

Told To The Public—What health departments in various cities and states think the public ought to know is revealed by the topics of press releases sent out. Among news releases received by the editor of this department this fall are the following titles:

Connecticut: "Midwife Institute"; "Does Your Child Grow?" "A Protective Measure"; "Poliomyelitis With Respiratory Paralysis"; "Sleep and Growth"; "Oyster Season Is Now On"; "Nutrition To Be Discussed"; also news about Department activities.

Detroit: "Prophylaxis of Ringworm for the Feet in School Children"; "Tuberculosis: An Important Cause of Death Among Children"; "The After Care of Infantile Paralysis"; "Toxoid as a Prophylaxis Against Diphtheria"; "Poliomyelitis"; "Diphtheria On The Increase—Why?"

Iowa: "Sewage Disposal"; "Wash Your Hands"; "Teachers Should Report Cases of Disease"; "Diphtheria in the Offing"; "Whooping Cough"; "A Fifteen-Dollar Blooded Calf"; "Heart Disease"; "Too Much Small Pox."

Maryland: "Oysters Are On The Menu Again"; "You Can Protect Them Against It" (diphtheria); "Defines Dental Decay"; "Seasonal Sickness"; "Health Insurance for the Six Year Molars"; "Don't Let These Things Go On"; "Start the Day With a Good Breakfast"; "Extension of Full-Time Health Service."

New York State: "Does It Make Any Difference What We Eat?" "The Closed Season For Garages"; "The Control of Communicable Diseases Among Children"; "Does

Your Child Have Good Teeth?—Regular Dental Attention Helps"; "Cancer"; "Swimming Pools and Their Effect on Health"

Oregon: "Health Problems of Swimming Pools"; "Food Poisoning"; "Rheumatism"; "Eating Sprees"; "The Control of Communicable Diseases Among Children"; "Prevent Colds"; "Report Diseases"; "Control Infantile Paralysis by Early Diagnosis and Prompt Treatment"

U S Public Health Service. "International Sanitary Relations of the U S P. H S"; "Rat-proofing of Ships"; "Preparing the Child For School"; "Cancer"; "The Prevention of Goiter"; "Sport For Health's Sake"; "Work of Employees' Mutual Benefit Association"; "The Fight Against Diphtheria"; "Hygienic Adjustment in Middle Age"

National Society for the Prevention of Blindness and New York City releases were not titled.

Of course many other city and state departments issued news material, and voluntary health organizations, of which none were received.

Write your own "moral," if any, to the above.

A New Medium—Gummed address-labels in red, black and white (cancer campaign symbol in white on black) are offered to contributors of \$1.00 or more to New York City Cancer Committee, 34 East 75th St., New York. The letter and reply slip carry the propaganda.

Radio in Racine—A series of 15 radio health episodes given by the Health Department, Racine, Wis., measure up well with the general run of commercial radio dramatized "sales talks." The conversation is easy, natural, entertaining and the propaganda worked in an ingenious, interest sustaining manner.

The subject is the safe and refreshing vacation of the Martin family. The mother is a sensible, cautious person, the father a hard working business man, the 18-year old George and the 15-year old Mary, modern young people with the gift of quick comebacks. The terse

conversation moves along with the good-natured chaffing heard in every family where real regard is covered with a veneer of sharp give and take.

First Mrs. Martin consults the Health Department about vacation precautions. Her plan for a long hike is changed to the use of the car with supplementary hikes, a warning against unusual unaccustomed exertions. We hear the family pack, treat sunburns, drive leisurely, pick camp, search for a pure water supply, all on advice previously obtained from their health department. Hear them have their little jokes while they guard their health:

Mary: I thought a scout was always observant.

George: Oh, did you? Well, they are. And they don't need signs and tags to tell 'em when a well is no good

Mary: I'm so glad you're not going to disappoint me

George: Aw, go climb a tree!

Mrs. M.: Well, anyway, George, if you didn't see those signs, why didn't you use the well water?

George: In the first place, the cover was made of boards, and they were dirty and rotten, and water could leak through them right back into the well. In the second place, the waste water wasn't drained away from the well. And the pump had to be primed—

Mrs. M.: Not when Mary tried it.

Mr. M.: Possibly that was because George and I had just primed it.

George: And—there was a barnyard up the hill from the pump. Did you see that, Mary dollink?

Mary: Eh—why, of course

George: Yes, you did—not!

Later they pick a clean restaurant through specific observations:

Mary: Well, here's your barbecue. Let's eat.

George: Does it pass the board of censors, Mom?

Father: It's got screens.

Mother: And the food is in glass cases.

Mary: So are the dishes.

George: And the girl back of the counter's got a clean apron.

Mary: What color hair has she got?

George: Brown. Sa—ay, what's it to you?

Mary: I just thought you'd surely notice that.

They visit relatives in a small town with a health hazard, typhoid fever. Arriving home well and refreshed, they find neighbors, who gaily omitted the precautions taken on their trip, ill with typhoid.

The series was interrupted once with an interesting episode designed to introduce the members of the Health Department giving the broadcast, including Dr. W. W. Bauer, who wrote the series, and Mrs. Bauer. An opportunity is made to describe the fine new quarters of the Health Department.—HELEN CAMPBELL.

NEWSPAPERS

The annual directory of newspaper feature syndicates appeared in *Editor and Publisher*, Times Bldg., New York. Aug. 29, 1931. 10 cents. Twelve health columns are edited by Drs. Copeland, Evans, Brady, Sophia Brunson, Clendening, Fishbein, McCoy, Galdston, Schumann and Bundesen. Editorial comment is offered by 12 syndicates. Some of the writers might use carefully selected material from health agencies. Crossword puzzles are supplied by 14 syndicates.

EDUCATIONAL MATERIAL

"An Important Message from the Health Commissioner" appears on the address side of a folded card, double postal card size. The inside is a type-written letter from the Commissioner of Health, New York State, addressed to "Dear Madam," urging increased milk consumption. Though reduced to the size of the double inside page the message is quite readable. It is distributed with the bills of milk companies.

Your Baby Needs Protection Now. Division of Health, Cleveland. 4 p. folder. Simplest possible statement about diphtheria and smallpox, with clinic information. The dark paper is a bit gloomy. *Free*.

Food for Children. Dept. of Agri-

culture, Washington. 20 p. Displaces Food for Young Children, a former Farmers' Bulletin. *Free*—while free edition lasts.

Four-fifths of the supply of Farmers' Bulletins is placed by law at the disposal of members of Congress for free distribution by them. It is therefore suggested that when Farmers' Bulletins are desired in quantity, request for them be made of a member of Congress.

The Health Guards. Canadian Dental Hygiene Council, Medical Arts Bldg., Toronto. 32 p. booklet; simply written; addressed to children and mothers.

Let's Grow—Be Healthy and Happy. Tuberculosis and Health Society, 51 Warren Ave., West, Detroit. 10 cents. 10 to-be-colored pictures of animals and birds illustrating 10 health rules, with jingles. One page shows penguins, and

Body straight and head erect
Is the posture to select.

Health Education Materials. Dairymen's League, 11 W. 42d St., New York. Revised catalogue.

Healthy Teeth. John Hancock Mutual Life Insurance Co., Boston. 11 pages. "Ought to do much towards giving men and women a basis for accepting or rejecting the truths or half truths with which they are bombarded." *Free*.

A group of booklets from Metropolitan Life Insurance Co., 1 Madison Ave., New York:

Good Habits For Children

Good Teeth

The Conquest of Typhoid Fever

First Aid

Above are revised editions, with new covers, and without distracting ornament on text pages. *Free*.

TITLES AND PHRASES

"From Stable to Table"—*Health*, New Haven.

"The Forty-Five Million" (children in U. S.)—*Mouth Hygiene Quarterly*.

"What Two Cents Accomplished." New York City Dept. of Health. Meaning the annual per capita expense for the 3-year diphtheria campaign closed last month.

"What One Can See In Figures"; "One or One Hundred?" "When a Thousand is Better Than Two Thousand"; "A Mountain Which Will Be Eaten Up"; "Things Which Make Things": some chapter headings from New Russia's Primer.

NEW

Birmingham's Health, Jefferson County Board of Health, Birmingham, Ala. Attractive printed front and back cover; 5 or 6 pages mimeographed monthly.

Health Finder, W. Va. Tuberculosis and Health Assn., Charleston, W. Va. Monthly.

The Junior Crusader, Wis. Anti-Tuberculosis Assn., 1018 N. Jefferson St., Milwaukee. 4 pages; punched for loose-leaf binder. Also used by Michigan Tuberculosis Assn. Monthly.

Mouth Health Quarterly. American Mouth Hygiene Assn., Essex Bldg., Minneapolis. \$4.00 a year. A distinguished Advisory Board and Board of Trustees. Type, paper and page-layout make for easy reading. Interesting illustrations of materials and methods from several countries

And farewell to *Missouri Public Health News*, State Dept., because of "the extreme decrease in the state revenue."

RADIO

Contrast the attention values of two radio titles (both addresses by the same educator!): "The State's Responsibility for the Education of Its Children" and "Safeguarding the Farmer's Best Crop."

Connecticut State Dept. broadcasts every Thursday, 1:25 to 1:30 p.m., via NTIC. Topics and speakers have been

announced from Sept. 3 to June 30. Copies of the talks will be sent upon request.

Some of the Conn. broadcast titles: "The Fall Crop of Brides," "Deferred Payment," "Watch Your Step," "The Sniffle Stage of Disease," "The Tragic Loss of Mothers," "Nagging," "Fat Mothers and Thin Children," "Before Germs Were Known," "Placing That Queer Member of Your Family."

Some titles from Dr. H. W. Haggard's popular Sunday night broadcasts: "Yellow Jack," "A Family Disease," "The Menace of Middle Age," "The Dancing Mania," "The Apothecary," "Athletics with Safety."

MAGAZINE ARTICLES

"Almost Every One Has Infantile Paralysis"—*Literary Digest*. Oct. 31, 1931.

"Disease, Its Cause and Prevention," by Prof. J. E. Greaves. *Science Monthly*, Lancaster, Pa. Nov., 1931. 50 cents.

"Eating for Good Looks," by H. R. Cades. *American Girl*, New York: Nov., 1931. 20 cents.

"How Long Will I Live?" by H. S. Cumming, M.D. *New York Herald-Tribune Magazine*. Nov. 1, 1931.

"Mental Hygiene in the Home." *Ladies' Home Journal*. Oct., 1931.

"New Styles in Diet As Well As in Dress," by E. F. Barnard. *New York Times Magazine*. Nov. 1, 1931.

MOUTH HYGIENE

Blazing a New Trail Through the Rockies. Canadian Dental Hygiene Council, Medical Arts Bldg., Toronto. Reports in some detail campaigns in British Columbia, Quebec and Manitoba.

"Educational Program on Dentistry for Children in Michigan," by W. R. Davis; "The Iowa Plan for Dental Health Education," by T. A. Gardner. *Journal of Amer. Dental Assn.*, 212 East Superior St., Chicago. Oct., 1931.

Healthy Teeth. 3 pages of mimeographed copy from League of Red Cross Societies, 2, Avenue Velasquez, Paris, VIII, France.

Suggestions for the Promotion of Mouth Health in Schools, by Bureau of Mouth Hygiene, Michigan Dept. of Health, Lansing. (No date.) 5 p. mimeographed; illustrated. *Free samples to health workers.*

The valedictory issue of *Missouri Public Health News* (Sept., 1931), Jefferson City, was a valuable special mouth hygiene edition.

MOTION PICTURES

The Canadian Tuberculosis Association, through the coöperation of the Dominion Motion Picture Bureau,

is assembling 16 mm. films of all new additions to Canada's tuberculosis sanatoriums together with black and white plans of one ward-floor in each building. The association hopes in this way to bring to the attention of sanatorium boards and others the advances being made in the construction of these new buildings.

"Why Willie Was Willing to Wash," National Motion Pictures Co., Indianapolis. 16 mm. and 35 mm. 1,000 feet. Disease dangers of dirt vs. cleanliness and soap.

"Golden Health." 1,000 feet. 16 mm. and 35 mm. Orange industry and "health-giving qualities." Address upon request.

"The kindest cut of all" (how to cut and edit an amateur movie); "Little touches" (details which create symbolism and picture-telling); "The title is dead; long live the title!" (in the amateur production); "Perfecting projecting" (how to show pictures better); these and other articles in October and November, 1931, issues of *Movie Mak-*

ers, 105 W. 40th St., New York. *Sample free.*

If you wish to locate amateur movie clubs in your city write to Arthur L. Gale, Amateur Cinema League, 105 W. 40th St., New York.

Arranging for a demonstration of the new superspeed film would provide a good excuse for getting together local amateur movie people connected with health and social welfare agencies, with others who might become interested in pictures for those organizations. The demonstration could include explanations of the new possibilities for taking indoor pictures.

POLIOMYELITIS

"Infantile Paralysis," by T. P. Gittens. *Monthly Bulletin*, Philadelphia Dept. of Public Health. Sept., 1931.

"Paralysis Immunity Gains—Adults Resist Infection," by Dr. Simon Flexner. *Health News*, New York State Dept. of Health. Sept. 14, 1931. Also, *New York Times*. Aug. 30, 1931.

READY-MADE NOVELTIES

If you want ready-made illustrations for holiday or seasonal issues of your bulletin or for other printed matter, costing from \$1.00 to \$3.50, the editor will supply addresses.

If ever, in a campaign, you wish to use door hangers, attractive cards to hang on door knobs, the editor of this department will supply you with an address for two-color blanks.

If you wish your Christmas cards to bear a really truly "Santa Claus" postmark write for address of one who will mail them—Santa Claus, Indianapolis.

If you want ideas for putting the holidays into your bulletin look up this department in the March, 1931, issue.

BOOKS AND REPORTS

Typhoid Fever. Its Nature, Mode of Spreading, and Prevention—By William Budd. *New York: American Public Health Association, 1931.* 200 pp. Price, De luxe ed., \$10.00; Reg. ed., \$5.00.

To attempt a critical review of a medical classic such as that before us would be a work of supererogation and smack of impudence. *It is sufficient to call attention to the fact that Budd was the first to recognize clearly the contagiousness of typhoid fever, the danger of polluted sewage and defective sewerage.*

This book was written some 8 years before the discovery of the germ of typhoid fever and 10 years before its isolation on solid culture media. The author was the first to point out the danger of disposing of typhoid fever discharges in such a manner that they could reach drinking water, and characterized it as criminal.

One sentence, with which he closes his summary, is of itself enough to make him immortal: "And he that was never yet connected with his poorer neighbour, by deeds of charity or love, may one day find, when it is too late, that he is connected with him by a bond which may bring them both, at once, to a common grave." Though he wrote this with particular reference to typhoid fever, it is applicable to all contagious diseases. We wish that this could be memorized by all medical students and social workers.

The present volume is published by the American Public Health Association for Delta Omega as the first of a series of reprints of public health classics. The text follows the original publication of 1874, with the exception of three errata noted by the publisher of the

original edition. "There have been printed from type by the George Grady Press, New York, eight hundred copies of this book, the first thirty-five of which have been printed on hand-made paper, numbered and bound in Persian Leather."

It is hard to speak too highly of this work, beautifully and interestingly written, and containing a wealth of facts gained by an epidemiological study which might well serve as a model to modern day workers. It deserves a place in all medical libraries. The original illustrations, one of them in colors, have been reproduced. The printing and make-up are exceptionally good, as befits the character of the text.

MAZÛCK P. RAVENEL

Nineteenth Annual Report of the International Association of Dairy and Milk Inspectors.

This, the 19th annual report of the association, includes the constitution, by-laws, program of the 19th annual convention, reports of committees, and papers read at the convention which was held in Cleveland, O., October 22-24, 1930.

Many important and interesting papers were read on bacteriological and laboratory studies and procedure; milk plant studies, including pasteurization time and temperature; inspection of milk plants; cleansing and sterilization of milk equipment; flavors in milk; milk content from farm to table; co-operation problems between inspectors and plants; and opportunities in the dairy industry. Others included one on a survey of the New York State milk and cream supply, one on undulant fever, and a report on such activities of

ceive new treatment; and the subject of selection is simplified.

Professor Castle's treatise on *Genetics of Domestic Rabbits* is of exceptional interest to laboratory workers who depend on these animals so widely for experimental use. Color and weight are both heritable characters and are significant as to laboratory usefulness and costs of maintenance respectively. Weight of the adult varies from 3 lb. in the Polish breed to 15 in the Flemish Giants. The genetic constitutions of about 58 genotypes designated as types or breeds by breeders, belonging to 11 major phenotypes, are tabulated and discussed in detail.

C. A. KORON

International Health Year Book, 1929—Published by the League of Nations, Distributed in the United States by the World Peace Foundation, 40 Mt. Vernon Street, Boston, 1930. 1504 pp. Price, \$8.00.

This is the fifth edition of the *Year Book*. It contains extensive vital statistics and deals with the public health progress of 40 countries and colonies during the year 1928.

Extensive tables present fundamental statistics for the various countries on area, population, movement of population, birth rates, mortality, causes of death, infant mortality, etc. Developments in the campaign against acute and chronic diseases are discussed as well as special public health activities such as training, child hygiene, water supply, waste disposal, sickness insurance, and rural health service. There is a discussion of public health legislation and budget for each country, and for certain nations general statements are presented concerning developments in the field of curative medicine, covering such topics as hospitals, dispensaries, pharmacies, medical personnel and the cost of medical care.

It is obviously impossible to secure data on all topics from every country

but the volume presents an excellent comparative summary with the more important health facts and activities of the various countries for the year in question.

C. E. TURNER

Jungles Preferred—By Janet Miller. Boston and New York: Houghton Mifflin, 1931. 321 pp. Price, \$3.50.

This is a fascinating story of a woman physician who after serving in Japan and China was asked to go to Belgian Congo. Although she is described as a "little brown sparrow of a woman," she underwent hardships which would have tried strong men.

Even as a book of travel and exploration it is fascinating, but from the medical standpoint, it gives an insight into the superstitions, unhygienic practices, and diseases of the Dark Continent, as well as their treatment and the results.

Dr. Miller has a keen sense of humor as well as a broad love for her fellow beings, which makes the book delightful. It can be highly commended not only to pass pleasant hours, but also for its wealth of information of that part of the world which is too little known, but filled with mystery and romance, and fast coming to be of enormous commercial importance.

MAZÛCK P. RAVENEL

The Mouth Health Quarterly, Vol. I, No. 1. Minneapolis: The American Mouth Health Association, October, 1931.

The growing recognition of the importance of oral hygiene is evidenced by the appearance of a new journal, *The Mouth Health Quarterly*, published by the American Mouth Health Association, with headquarters in the Essex Building, Minneapolis, Minn.

The first number contains a number of excellent articles by doctors, dentists, nurses, and students of nutrition. It is attractively gotten up and beautifully printed.

MAZÛCK P. RAVENEL

A Text Book of Medical Diseases for Nurses—By Arthur A. Stevens, M.D., and Florence Anna Ambler, B.S., R.N. Philadelphia: Saunders, 1931. 503 pp. Price, \$2.75

In this latest contribution to the field of medical nursing, we have not only an interesting and readable book, but a complete, clear and concise presentation of the medical aspect of disease. The subdivisions of chapters are captioned—Definition, Etiology, Symptoms, Pathology, Complications, Prognosis and Treatment, in logical sequence.

Complementing this able discussion of disease, Miss Ambler in simple and direct phraseology describes in detail the nursing care of the patient.

It is this combination of the medical aspect of the disease with the latest and most approved method of nursing care, which makes this a valuable text for the student in the school of nursing.

To the graduate nurse, who has not recently had opportunity for a refresher course, this book is recommended. For her the matter of the appendix which describes the nursing procedures used in the Philadelphia General Hospital will be of interest and value.

This book covers a broad field and leaves little to be recommended other than the addition of more illustration and graphs.

MARY W. J. W.

BOOKS RECEIVED

A TEXT-BOOK OF ORAL PATHOLOGY FOR STUDENTS AND PRACTITIONERS OF DENTISTRY By Russell W. Bunting. Philadelphia: Lea & Febiger, 1929. 495 pp. Price, \$7.00

GYNECOLOGY AND UGEOLOGY FOR NURSES By Samuel S. Rosenfeld. New York: Wood, 1931. 230 pp. Price, \$2.00.

SOCIAL POLITICS AND MODERN DEMOCRACIES By Charles W. Pipkin. New York: Macmillan, 1931. Two Vols. Price, \$7.50

A SYSTEM OF BACTERIOLOGY IN RELATION TO MEDICINE. Vols VI and IX. London: His Majesty's Stationary Office, 1931. Price, Each \$6.00.

HEALTH THROUGH LEISURE-TIME RECREATION By Edith M. Gates. New York: The Woman's Press, 1931. 216 pp. Price, \$2.50

CANCER AND RACE. By Maurice Sorsby. New York: Wood, 1931. 129 pp. Price, \$1.00.

AN INTRODUCTION TO MATERIA MEDICA. Drugs and Solutions. 3d ed. By Stella Goostrey. New York: Macmillan, 1931. 214 pp. Price, \$1.75.

SCHOOL VENTILATION. PRINCIPLES AND PRACTICES. New York: Commission of Ventilation. New York: Teachers College, 1931. 73 pp. Price, \$1.00

SCHOOL NURSING—A CONTRIBUTION TO HEALTH EDUCATION. By Mary Ella Chayer. New York: Putnam, 1931. 292 pp. Price, \$2.50

MARKET MUSIC. 2d ed. By Ernest Kell, and Clarence E. Clement. New York: Wiley, 1931. 455 pp. Price, \$4.50

THE NURSES' MEDICAL LEXICON. By Thomas Lathrop Steadman. New York: Wood, 1931. 679 pp. Price, \$1.75

LESSONS IN MATHEMATICS. By Frederick M. Harrell. New York: Association Press, 1931. 308 pp.

PREFATION OF SCIENTIFIC AND TECHNICAL PAPER. By Sam F. Treloar & Emma Susetta Yule. Baltimore: Williams & Wilkins, 1930. 117 pp. Price, \$1.50

NOISE AND VIBRATION ENGINEERING. By Stephen E. Stearns. New York: Van Nostrand, 1931. 171 pp. Price, \$2.75

THE CONQUEST OF OLD AGE. By Peter Schmidt. New York: Dutton, 1931. 397 pp. Price, \$5.00

PSYCHOLOGY SUBJECT OF SHORT-TIME. By Grace Adams. New York: Cornell-Elmer, 1931. 259 pp. Price, \$2.50

CHILD HEALTH AND THE COMMUNITY. By Courtney Dinsdiddle. New York: Commonwealth Fund, 1931. 80 pp. Price, \$1.75

THE CARE AND FEEDING OF ANIMALS WITH DOUBTS ABOUT CHICKENS. By Louis C. Henderson. New York: Dutton, 1931. 274 pp. Price, \$2.50.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Tuberculosis Relief and Prevention—The amount of relief available to tuberculous families in Syracuse is inadequate, and without effective relief medical care cannot fulfil its possibilities. What relief is given is unrelated to the needs of tuberculosis prevention and good social service. As conditions are much the same the country over, the solution offered may be generally applicable.

BURRIT, B. B. Social Service and the Relief of Tuberculous Families. *Milbank Quart. Bull.*, 9, 4: 147 (Oct.), 1931.

Russian Public Health—Reporting briefly on conditions observed during a short visit, this account by a British medical officer gives every evidence of being dispassionate and true; therefore, it seems a significant contribution.

CRITCHLEY, A. M. Public Health in Russia. *Med. Off.*, 46, 14: 147 (Oct 3), 1931.

Yellow Fever—The last word on the means by which yellow fever is spread and the accepted preventive measures is summarized in this address.

CUMMING, H. S. Present-Day Problems in Yellow Fever. *Pub. Health Rep.*, 46, 40: 2361 (Oct. 2), 1931.

Transmission of Typhus Fever—Evidence is presented pointing to the rat flea as a common vector of endemic typhus from rat to rat and man to man.

DYER, R. E., *et al.* The Experimental Transmission of Endemic Typhus Fever of the United States by the Rat Flea *Xenopsylla Cheopis*. *Pub. Health Rep.*, 46, 42: 2481 (Oct. 16), 1931.

Racial Susceptibility to Communicable Diseases—Significant differences are found in death, case and fatality rates for diphtheria and scarlet fever and measles death rates among several

racial groups under uniform conditions of contact exposure.

EMERSON, H. Significant Differences in Racial Susceptibility to Measles, Diphtheria and Scarlet Fever. *J. Prev. Med.*, 5, 5: 317 (Sept.), 1931.

Mechanisms of Immunity—A series of papers discussing the phenomenon of immunity from the standpoints of tissue resistance, sub-clinical infections, and humoral elements. Although this series is not a formal symposium, the papers, read in succession, constitute an inclusive presentation of this difficult subject.

GAY, F. P., *et al.* Tissue Resistance and Immunities. *J. A. M. A.*, 97, 17: 1193 (Oct. 24), 1931.

Nutrition and Puerperal Infection—Every second woman in an out-patient prenatal group was given an extra supply of vitamins A and D. These women had a greatly reduced incidence of puerperal sepsis over the control group.

GREEN, H. N., *et al.* Diet as a Prophylactic Agent Against Puerperal Sepsis. *Brit. M. J.*, 3691: 595 (Oct. 3), 1931.

Diphtheria Contacts and Carriers—Of 3,449 contacts, 11.7 per cent were found positive. Of those negative at the first test, 13.4 per cent were found positive after 10 days. Many other significant findings are included in this Baltimore study.

KUSAMA, Y., and DOULL, J. A. Carrier Infection Among Family Associates of Diphtheria Patients. *J. Prev. Med.*, 5, 5: 369 (Sept.), 1931.

Computing Maternal Death Rates—What determines the cause of maternal deaths?—the statement of the physician, the registrar, the code of

rules, or the exceptions to the rules? Is there a way of determining rates better than deaths per 1,000 births? In the light of acknowledged disparity, should comparative national rates be computed in tenths of a per cent? Are we justified in comparing selected group experience with the country at large? Here are some provocative questions, the answers to which should be considered by all sanitarians who have regard for the truth.

LOWRIE, R. J. The Maternal Mortality Rate Computed and Standardized by a New Method. *New York State J. Med.*, 31, 19: 1189 (Oct. 1), 1931.

Estimating Nutritional Status—Proposing a width-length factor by which the usual height-weight-age tables can be made more nearly true indices of nutritional status. An important contribution.

LUCAS, W. P., and PRYOR, H. B. Physical Measurements and Physiologic Processes in Young Children. *J. A. M. A.*, 97, 16: 1127 (Oct. 17), 1931.

Cancer Immunity Research—Reporting from London limited but promising studies in immunity against implanted mouse tumors.

LUMSDEN, T. The Problems of Cancer Treatment and Research with Special Reference to Tumor Immunity. *J. State Med.*, 39, 10: 577 (Oct.), 1931.

Heart Disease in Children—This study of San Francisco school children, of whom 2 per cent were reported as cardiac suspects, reveals many interesting conditions. Scarlet fever and diph-

theria are apparent factors causing organic heart disease.

RICHTER, I. M. Incidence and Variety of Heart Disease in School Children of San Francisco. *J. A. M. A.*, 97, 15: 1060 (Oct. 10), 1931.

Applied Sex Hygiene—Excellent indeed is this straightforward account of what a school nurse really can do in the treatment of sex problems. Worth a bushel of vague generalizations on social hygiene.

SMALLEY, R. The School Nurse Meets Social Hygiene Problems. *Pub. Health Nurse*, 23, 10: 475 (Oct.), 1931.

Preventing Diphtheria in Bridgeport—If you read this conclusion you will not be satisfied until you have read the whole paper. "We believe that the immunization treatments are no more important in the reduction of diphtheria in Bridgeport than the three administrative measures listed above (multiple negative release culture, bacteriological examination of every possible contact, selection of most effective culture medium)."

WILD, W. F., and TIRRELL, K. R. Diphtheria Control in Bridgeport, Connecticut. *J. Prev. Med.*, 5, 5: 303 (Sept.), 1931.

Studies in Health Education Results—Can general health education propaganda be made to pay dividends, or would the money and effort be better spent on direct preventive measures? An answer to the question is found in this Bellevue-Yorkville study.

ZIMAND, S. Campaign Calendar of a Public Health Organization. *Milbank Quart. Bull.*, 9, 4: 165 (Oct.), 1931.

NEWS FROM THE FIELD

RECOMMENDATIONS OF THE COMMITTEE
ON EMPLOYMENT PLANS AND SUG-
GESTIONS, CHICAGO, ILL., OCTOBER
26 AND 27, 1931

AMONG the recommendations of
this committee are the following:

RECOMMENDATION NO. 1.—RESUMPTION OF WORK

United National Action to Encourage
Every American Citizen Now Employed
to Resume Normal Buying—To Use
Available Income to Purchase Goods
Normally Needed and in the Replace-
ment of Which Labor is Employed—Is
a Condition Precedent to Any Hopeful
Program to Constructively Increase Em-
ployment; Continued and Further Re-
striction of Consumption of Goods and
of Expenditures for Improvements and
Replacements Inevitably Will Offset
Any and Every Effort for Emergency
Relief.

RECOMMENDATION NO. 4.—SPREAD WORK

The Spreading of Available Work in
Industrial, Commercial, and Professional
Enterprises Still is the Most Fruitful
Field for Immediate Unemployment Re-
lief. Workers Have Generously Shared
Hours of Labor and a Substantial Pro-
portion of Employers Have Given Ear-
nest and Sincere Coöperation, but Abun-
dant Evidence is at Hand that a Large
Number of Employers Have Not Re-
sponded. Therefore, the Committee Re-
news its Recommendations of September
28.

RECOMMENDATION NO. 6.—PUBLIC WORKS

The Committee Urges That Nothing
be Omitted to Make Immediately Avail-

able New Additional Employment Rep-
resented by Public Work Already Au-
thorized and Appropriated for but
Delayed or Blocked by Removable
Legal Obstacles and Supervisory Red
Tape.—The President's Organization on
Unemployment Relief, WALTER S. GIFF-
ORD, *Director*, 1734 New York Avenue,
Washington, D. C.

CANADIAN RESEARCH COUNCIL MEETING POSTPONED

THE Canadian National Research
Council announces that the Fifth
Pacific Science Congress, planned under
the auspices of the Canadian National
Research Council, in Victoria and Van-
couver, British Columbia, between the
dates May 23 and June 4, 1932, has
been postponed for a year.

HYGIENE AND BATHS

THE American Association for Hy-
giene and Baths held its 1931 Con-
vention at the Webster Hall Hotel in
Detroit, Mich., November 6 and 7,
under the auspices of the Detroit De-
partment of Health with the coöperation
of the Michigan State Department of
Health.

JOHN HANCOCK ISSUES NEW BOOKLET

THE great variety of functions
through which the modern city
health department prevents the spread
of disease and promotes the health of
the people it serves are set forth in a
new booklet, *Your Friend, the Health
Officer*, issued by the Life Conservation
Service of the John Hancock Mutual
Life Insurance Company, Boston, Mass.
This contribution to the support of the
modern health program was written by

Dr. Wilson G. Smillie, Professor of Public Health Administration, Harvard University Medical School.

This new booklet is available for immediate distribution to health officials.

SEWAGE WORKS ASSOCIATION MEETING

THE fall meeting of the New York State Sewage Works Association was held at Ithaca, N. Y., October 16-17, President J. F. Skinner presiding. The total registration of members and guests was 96. Among the papers presented were—Sedimentation Tank Design and Performance, by Glenn D. Holmes, and a Symposium on Stream Pollution, participated in by Professors Chamot, Needham, and Classen, of Cornell University, and Dr. Emmeline Moore, of the New York State Conservation Department.

TEXAS PUBLIC HEALTH ASSOCIATION MEETING

THE Texas Public Health Association held its annual meeting in Houston, November 9-13. Dr. A. C. Hutcheson, City Health Officer, and Dr. H. K. Read, president of the Association, Houston, were joint directors of

the meeting. There were two days of laboratory work, one day devoted to round table discussions of the Texas drought relief health program, malaria control, and county unit work. One evening session featured unemployment relief measures, and two days were devoted to various public health problems.

PSYCHIATRY

A NEW Division of Psychiatric Education has been created in the office of The National Committee for Mental Hygiene, with the aid of The Commonwealth Fund, The New York Foundation, and The American Foundation for Mental Hygiene, all of which have contributed to the support of the project.

The Division is under the immediate direction of Dr. Ralph A. Noble, of Sydney, Australia, who has a wide knowledge of psychiatric education in Europe and America and was invited to this country to inaugurate the work of the new Division and to take active charge of the program; and associated with him is Dr. Franklin G. Ebaugh, Director of the Colorado State Psychopathic Hospital, who is familiar with psychiatric training problems in this country and has given the subject special study.

PERSONALS

DR. CHARLES WARDELL STILES was retired from active duty in the U. S. Public Health Service on October 1, after more than 40 years of service in the government. Dr. Stiles' many friends took this occasion to extend to him a dinner, which was held at the Cosmos Club, November 7.

DR. L. D. BRISTOL, Member A. P. H. A., of New York, Health Director of the American Telephone and Telegraph Company, has contributed the Chapter on Health in the *Handbook on Business Management*, recently

published for the American Management Association.

MAJOR G. C. DUNHAM, formerly of the Medical Field Service, U. S. Army, Carlisle Barracks, Carlisle, Pa., is now located in the Office of the Governor General, Philippine Islands, Manila.

DR. A. JUDSON KEMPER has been appointed Health Officer of Harrison County, W. Va., to succeed Dr. V. A. Selby, Member A. P. H. A., retired.

DR. R. S. PATTERSON has been appointed representative of Public

Health Education Section on the A. P. H. A. nominating committee.

EDWARD F. BROWN resigned as executive of New York's Diphtheria Prevention Commission, thus closing the 3-year program which reduced cases about 56 per cent and death rate about 30 per cent.

HORACE HUGHES is now in New York as administrative assistant, Tuberculosis and Health Committee, State Charities Aid Assn., with special reference to health education and publicity.

JOHN W. KELLY is director of health education, Kentucky State Board of Health.

HARRIET L. PARSONS has become educational assistant, Massachusetts Society for Mental Hygiene.

CONFERENCES

January 22-23, American Social Hygiene Association, New York, N. Y.

April 4-8, American College of Physicians, San Francisco, Calif.

April 11-15, American Nurses Association, San Antonio, Tex.

April 11-15, National Organization for Public Health Nursing, San Antonio, Tex.

June 6-9, National Tuberculosis Association, Colorado Springs, Colo.

July, The Second International Conference of Social Work, Frankfurt, Germany.

September 6-9, Annual Meeting of the International Union Against Tuberculosis, The Hague, Holland.

WHY B-K IS THE BEST STERILIZER

B-K is a standardized sodium hypochlorite solution in a concentrated form . . . B-K has a quick-acting, germ-killing power, many times more powerful than carbolic acid . . . B-K is soluble in water and as efficiently active in cold water as in warm water . . . B-K is clear and free from oil, acids and poisons . . . and harmless to equipment and human tissues. B-K is dependable—easy to get—easy to use—and very economical. Leading organizations of public health recommend B-K as a highly effective sterilizer of dishes, glasses and silverware in public eating and drinking places.

Interesting data will be sent on request.

GENERAL LABORATORIES, INC.
1230 Dickinson Street, Madison, Wisconsin

B-K is a quick-acting germ-killer . . . always uniform in quality, positive in results and manufactured under the strictest laboratory control.
